SIR,—Feeling the great importance of the work I have in hand, and the necessity for continued action, I must beg to trespass on your further kindness in permitting me again to address a few words to my professional brethren, the Poor-law surgeons. I desire to acquaint them of the fact that five of the six Medical Officers of this (the Amersham) Union have now subscribed 5s. each towards the two funds, making 25s. in all. The remaining officer is very ill, and has not been applied to. Now, there are no less than 650 unions in the country, and if each union furnished a proportionate amount to the above, we should have in possession the very respectable sum of 812*l.* 10s.—an ample supply for both the purposes we require, viz., the expenses of the Reform Association and the testimonial to our chairman. I regret to see that no exertion has been made in the several unions to obtain subscriptions for these purposes, and in particular a testimonial to Mr. Griffin. Surely this is as opportune a moment as any for doing something in the way of thanks, and, I will say, of recompense for the nine years of continued and unrelaxed efforts of Mr. Griffin, to gain, both for the poor and ourselves, something like justice at the hands of the Government. Were the scheme which he proposes to become law, it would prove a social and economical benefit to all classes of the community; that he has not succeeded in obtaining this measure of justice is no fault of his, but rather to be laid to our own charge, and is no argument against our presenting him with the very inadequate acknowledgment which I lately proposed, and which I would fain see carried out. I suggest that collections be made in each union, and that the sums so collected be forwarded to one or other of the offices of the 'Lancet,' the 'Medical Times and Gazette,' or the MEDICAL CIRCULAR.

I sincerely trust that gentlemen will now use every effort to second my views, and to obtain for Mr. Griffin a suitable present, which he so richly deserves. I had intended making a written application to every individual member of our body; but the expense and labour of so doing would have been so great, that, for the present, these considerations have deterred me. I hope, moreover, that immediate action on the part of my friends will render it unnecessary for me to do so.

I am, Sir, &c., WM. PROWSE.

GARIBALDI AND THE MEDICAL PROFESSION.

To the Editor of the Medical Circular.

SIR,—As you are well aware, the Medical Profession has, within the last few years, been subjected to many severe remarks on account of the apparent differences existing amongst its members; I need only refer to the cases of Palmer, Smethurst, Townley, and others, which will readily occur to you and your readers.

The case of Garibaldi is a striking instance of this difference of opinion. It was first stated that the hero was coming to this country for change of air and the benefit of Medical and Surgical advice, and it was said he intended to place himself under the care of Mr. Fergusson. This certainly had the appearance of a slight to Mr. Partridge, who, as you of course remember, went twice to Caprera to attend him. It was then denied that he required Medical advice at all, and the next notice on the subject was a letter from Mr. Partridge saying that he had visited the General, and found him in good health and his wound healed. The fatigue which Garibaldi underwent for a few days seemed to bear out the views of Mr. Partridge; but all of a sudden a letter appeared from Mr. Fergusson informing the public that Garibaldi was much out of health, and that further excitement might be fatal. Garibaldi's own physician met this assertion of Mr. Fergusson's with a flat contradiction, and Garibaldi himself has not, in the slightest degree, alluded to his health having failed him, but rather speaks in the reverse. Now, if the General came to England for Medical and Surgical treatment, why was his visit so abruptly terminated?

It is not worth while to take up your columns with political matters, but no reasonable man can doubt that *he was compelled to leave by Ministerial interference;* otherwise, he could have selected hundreds of places in this country to rest and recruit. The question to be considered is, Has there been any sacrifice of professional opinion to suit the exigencies of the hour, or has there been any breach of professional etiquette? Mr. Fergusson is imperatively called upon to inform the world why, and on what grounds, he repudiated the opinions of Mr. Partridge; and Mr. Partridge, in justice to himself, is bound to give his version of the affair.

The honour and dignity of the Profession suffer most materially in public estimation by these unseemly differences; and it is sincerely to be hoped that immediate explanations will be given by all parties mixed up in the matter, and that common sense will have the opportunity of deciding

"When doctors disagree."

Yours, &c., D. G. H.

April 23rd.

[This letter reached us after our last number had gone to press, or it would have appeared last week.—ED. MED. CIRCULAR.]

OBSTETRIC GUIDE-HOOK.

To the Editor of the Medical Circular.

SIR,—Will you allow me, for the sake of your readers who have corresponded with me in respect of your report of the proceedings of the Obstetric Society, to say, that the "Guide-Hook," on the use of which, through the kindness of Dr. Graily Hewitt, I communicated a paper to the Society, is made by, and may be procured of Messrs. Weiss and Son.

I earnestly commend the instrument to the notice of every accoucheur, and shall be greatly favoured by the experience of any who may make use of it.

I am, &c., SAMUEL NEWHAM.

Bury St. Edmund.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

April 19th, 1864.

Mr. Prescott Hewett, President.

Dr. Graily Hewitt read a report on a case exhibited by Dr. Schuloff as a specimen of two fibrinous casts of the uterus. He found the two bodies exhibited to be coagula moulded to the form of the uterus, and proceeding from some morbid formation in the uterus. The outer part of the clots was much discoloured, giving rise to the appearance of a fibrinous lining.

Dr. Wilks exhibited a specimen of

RUPTURE OF THE HEART.

This was presented to the Society for Mr. Roper, of Shoreditch; and the principal point of interest was, how far the surgeon and the public were justified in attributing the patient's death to starvation. The patient was a woman about sixty years of age, and was endeavouring to subsist upon a few pence a week in a lodging containing no fire, and having no clothes to cover her. She died suddenly, and there was found a laceration through the left ventricle, the coronary artery being diseased, and the muscular tissue pale and soft. There were sufficient morbid conditions found in the organ to account for the rupture; but at the same time Dr. Wilks thought that an impoverished condition of the blood might have aggravated the tendency to muscular degeneration, and that the remarks of Mr. Roper before the coroner were quite reasonable: that the deceased died immediately from rupture of the heart, but that privation, want of nourishment, proper clothing, and warmth, undoubtedly accelerated the fatal event. There was no trace of fat in the interior of the body.

Dr. Harley doubted whether inanition could predispose to rupture of the heart. This lesion was usually met with in persons well fed, and otherwise in good condition.

Dr. Quain allowed that inanition might produce a general weakening and softening of the heart, which would induce its sudden stopping; but rupture was caused by local softening of some small portion, and not by general degeneration. He thought the rupture was produced by disease of the artery leading to the softened part of the heart.

Dr. Wilks also showed some specimens of

LARDACEOUS DISEASE OF THE VISCERA,

consisting of the liver, spleen, and kidneys, of a young man who had long suffered from this disease. The point of interest was in the fact that on the surface of the liver, where it was adherent to the diaphragm, there was a layer of pure lardaceous material almost an inch thick. In this no trace of hepatic structure was visible, and it thus seemed like a free deposition of the adventitious material on the outside of the organ.

Dr. Wilson Fox believed that hepatic tissue existed in the layer described as a free deposit.

The President related a case in which a large stone lodged in the pelvis of the kidney, and in which the kidney was drawn down into the right iliac fossa—not, however, movable.

Dr. Harley exhibited a drawing from a case of

RENAL CALCULUS.

The subject was a gentleman aged sixty. Only one kidney was affected. A very large number of small calculi were found in the kidney, but there was also a very large one, which perhaps partially obtructed the pelvis, and probably prevented the passage of any of the smaller calculi into the bladder. No symptoms had been produced, and the affection was unsuspected during life.

Mr. Squire exhibited a specimen of the Pediculus Corporis, to the presence of which animal he attributed the existence of prurigo senilis.

Mr. Spencer Wells exhibited some microscopic sections from a case of

CANCER OF THE OVARIES,

in a girl aged thirteen. The tumour had grown with great rapidity, and was accompanied by a certain amount of dropsy.

Another case of the same disease, the patient being of the age of fifty, presented two tumours, one on either side of the uterus. The cachexia and great rapidity of growth sufficed for diagnosis, and prevented any operation being attempted.

The third case was also accompanied by ascites, and here also the constitutional and local symptoms were sufficient to dissuade from ovariotomy.

OVARIOTOMY.

Mr. Spencer Wells also displayed a preparation from a patient who died three days after ovariotomy. The pedicle had been tied, the ligature cut off short and returned into the abdomen. The patient died of peritonitis, radiating from the tied pedicle. The wound was closed, and no peritonitis existed around this. Mr. Wells has, however, pursued this course with success in three cases lately, the patients being in good health, and believes that in these cases the ligature becomes encysted by lymph. One patient went into the country fifteen days after operation.

Mr. Spencer Wells also referred to a case in which tubercles were found beneath the peritoneal coat of an ovarian cyst. The patient died five days after ovariotomy, of diffuse peritonitis. Some of her relations had died of tubercular diseases.

Dr. Wilson Fox described this specimen at greater length.

Dr. Murchison exhibited for Dr. Gairdner, of Glasgow, a specimen of

DISEASED SUPRA-RENAL CAPSULE,

with bronzing of the skin, or rather dark discolouration. The patient was a lad fifteen years of age, who had suffered from anæmia and discolouration of the skin for about a year and a half, followed by a pain in the back, diarrhœa, and vomiting. The face and whole body was tinged deeply, and in some places almost to a negro blackness. The immediate cause of death was erysipelas of the face. On post-mortem examination, recent tubercle was found in the peritoneum, and old tubercle in the lung. All the other viscera were healthy, except the supra-renal capsules, both of which were much enlarged and indurated, and were totally disorganized, being replaced by hard masses of a cheesy substance, exactly resembling soft tubercle, and containing a cretaceous matter here and there. The existence of Addison's disease was diagnosed during life.

Mr. T. Smith exhibited an

ARM AFFECTED BY ELEPHANTIASIS,

which was removed by amputation from a young woman aged twenty, and weighing twenty-four pounds. The place where the incision was made was not hypertrophied, and it rather looked as if a ligature had been tied around the arm.

The specimen was referred to Mr. Hutchinson and Mr. T. Smith.

Mr. Hinton showed the

PETROUS BONES

from a girl who died from diphtheria. There had been fetid discharge from the ears, and the bones were much softened, rough, and inflamed. There was universal arachnitis. Mr. Hinton attributed the arachnitis to inflammation spreading up through the bones.

Dr. Gibb exhibited some

WORMS EXPELLED FROM THE NOSE AND FRONTAL SINUSES

of a girl aged eleven years. For three months she complained of pains in her head and over the frontal sinuses, and also in the chest. The face, forehead, and nose then became swollen and erysipelatous, with a discharge from the nose, and the passage of several worms, which were believed to come from the frontal sinuses. They were exceedingly small, about an inch long, and when coiled up were not larger than pins' heads. The girl is still under treatment in the Westminster Hospital.

Mr. Mason inquired if Dr. Gibb had seen any of the worms passed.

Dr. Gibb said that he had seen them come from the right nostril.

THE MEDICAL CIRCULAR.

WEDNESDAY, MAY 4, 1864.

THE MEDICAL DEBATE.

The last time Parliament had occasion to discuss the Medical Act the first question that was put was the question of admitting the Lay Press to the Meetings of the Council. This question has been decided in the affirmative, as we expected, and I trust that it will be found that the chief opposition to the principle has been removed from the Council. The matter of the Resolution that happened to be submitted was Dr. Andrew Wood, who made a valiant and entertaining speech on the occasion; and we readily admit that in our opinion the Council has done wisely in removing the point. It was very properly urged by Dr. Andrew Wood that the Council had nothing to conceal from the Profession, and that the system of publicity now universal in all representative bodies might with advantage be followed by the Medical Council, which was, in fact, the representative of some 6,000 persons. Whether the general Medical or lay reader will think it expedient or advantageous to publish all the speeches which the Members of Council may think fit to make, and whether the Profession will have time or inclination to read them, are matters of little consequence: the very fact that the doors are thrown open, and that publicity is given to the proceedings, will show that the Members of the Medical Council are desirous to make themselves popular with their constituents, and that they are honestly labouring in the path of duty to which they have been elected.

Some of our contemporaries, who look but and hold as the minority were then, sometimes extol the Medical Council as the most useful and valuable Medical Institution in Great Britain; and at other times hold it up to contempt as a useless incumbrance and a downright failure, involving an enormous waste of money extracted from the pockets of an over-worked and ill-paid Profession.

They sometimes blame it for not doing things which it has no power to accomplish, and for not attempting reforms which it was never intended to promote; and in the case of the compilation of the British Pharmacopœia, many censures of a most needless character have been offered against the execution of a task which, in its very nature, was extremely difficult.

In one respect we fear that the Profession have greatly deceived themselves—namely, as to the powers of the Medical Council in suppressing illegal practice. It really possesses no such powers; nor would the Act of 1858 have ever passed the Legislature if any had been demanded. The fact is, that quackery has such a strong hold upon the British public, and individual quacks are so largely patronized by many members of both Houses of our Legislature, that any effort to suppress empiricism would certainly be unsuccessful. The only point gained in this direction was the power of printing a Register containing the names of those who had passed a Medical examination, and thus distinguishing qualified Medical men from those who were unqualified. But it will be recollected that no power whatever was granted to punish or molest the latter; and even in the case of names in the Register, no authority was given to exclude any on the ground of practising in a heterodox manner. Thus, the practitioners of Homœopathy, Hydropathy, and other forms of quackery, were directly protected and encouraged by the Medical Act; and it is useless to deny that, in the present temper of the Houses of Parliament, there is no prospect whatever either that illegal practice will be suppressed, or that intra-professional quackery will be abolished.

It must be admitted that the first specimen we have of the published debates in the Medical Council is not particularly edifying, and is not very satisfactory as to the knowledge of business, or the courtesy of speech exhibited by the members. Nearly the whole of Monday and Tuesday in last week was occupied by the question whether reporters should be admitted, the decision being ultimately, as we have stated, in the affirmative. On Wednesday, the Council resolved itself into a Committee of Education, and, difficult as it was to understand formerly the meaning of the amendments upon amendments made upon the original resolutions, it is not more easy to understand them now, with all the advantage we may be supposed to possess from the personal explanations of the speakers. We may the less hesitate to avow our difficulties in this matter, as we find, in the case of a discussion occupying the greater part of the day upon a resolution and an amendment, that Dr. Storrar frankly avowed he could see no difference between them; and after full consideration of both motions, we are entirely of Dr. Storrar's opinion. It is very probable that in moving amendment upon amendment, often differing apparently only in words or in the order of the sentences, the speakers have some occult object in view, and wish either to throw dust in one another's eyes, or to promote some favourite object of their own; or it may be that, knowing how much money is paid to the members of the Council, each one thinks he ought to earn his honorarium by a proper amount of speaking. But, however it may be, the fact is as we state it, that there is an intolerable amount of talk in proportion to the work done. The proposition, on the occasion to which we refer, was simply that "the committee should consider the recommendations relating to general and professional education," and the amendment was that "the Council consider the whole subject of Medical examination with the view of preparing a report."

The discussion, however, called forth a vigorous speech from Dr. Andrew Wood, who vindicated the powers of the Medical Council in prescribing general rules as to professional education and examination, which should be binding upon all the educational and examining bodies; and who alluded very pointedly to the London College of Surgeons as having set the example of refusing conformity with the Recommendations of the Medical Council, and thus rendering the deliberations of the latter body entirely nugatory. This philippic called forth Mr. Arnott, the representative

of the London College of Surgeons, who certainly made a very lame apology for that body, thus making manifest the serious loss which it must have sustained in the removal of Mr. Lawrence, the eloquent and thick-and-thin supporter of the corporation in Lincoln's inn fields. In fact, Mr. Arnott's speech was *apropos* to nothing, except that the College did not think it convenient to comply with the Recommendations of the Council, but offering no reasons for its non-compliance.* In answer to Mr. Arnott, Dr. Alexander Wood, the President of the College of Physicians of Edinburgh, accused Mr. Arnott (a Scotchman settled in London) of abusing the Scotch, adding that whenever he heard a man abusing Scotland, he was sure that that man's grandfather was a Scotchman. This sally excited considerable laughter, to the discomfiture of Mr. Arnott; but what it had to do with the discussion, or how far it was compatible with the decorum of debate, we are unable to understand. Eventually, after all this talking, the original resolution was carried, namely, that the Council should proceed to business—a question which might have been settled in a few minutes.

DEBATE IN THE MEDICAL COUNCIL ON MEDICAL EDUCATION.

The Medical Council is now engaged in the discussion of the very important subject of Medical Education, Mr. Syme having proposed a resolution that it is expedient to frame a Course of Study for Medical Education, which may be recommended to the Licensing Boards. To this an amendment has been proposed, defining some of the essentials in every scheme of education and examination.

In the interesting debate which ensued, Dr. Parkes, in the course of a very eloquent speech, which made a great impression upon the Council, insisted on the necessity of defining in some measure the amount of information which ought to be required of all candidates for a Medical or Surgical diploma. As an instance of the laxity with which diplomas and licences are granted, Dr. Parkes referred to his own experience as an examiner for the Competitive Examination for Medical Commissions in the Army, and he stated that in some instances it had been found that candidates were grossly ignorant even of Anatomy, and very frequently of Chemistry. Some of them were unable, when required to pass a catheter or put up a fracture, to perform either of those operations. Both he and Mr. Busk, who is also an examiner for the Army Service, thought that the state of Medical education was very unsatisfactory, and that, at the very least, the examination should be sufficiently stringent to prove that the candidate was not dangerous to be sent forth to the public. Dr. Parkes thought that the Council ought to reform the methods of examination at present in use, and should institute a scheme of supervision over the Examining Boards.

Dr. Sharpey coincided in many respects with what had been advanced by Dr. Parkes. He was once present at an examination for candidates in the Army Medical Department, and he found many of the candidates very badly prepared. One was asked to tie the subclavian artery, and he tied the omo-hyoid muscle! But he did not wish to promote uniformity of education and examination at the sacrifice of freedom of action, but thought that much must be left to individual judgment; and, above all, a dull mediocrity must be avoided. There can be no doubt that every candidate for a diploma or licence should be of the age of twenty-one, and that four years should be the minimum period of professional study. But the question arises whether in any existing case the curriculum is deficient, or any where it is in excess and ought to be reduced. He thought that the Council should not define the curriculum of study, but that it should be left to the judgment of each corporate body to lay down its own curriculum. Nor ought the Council to prescribe an order of study which must necessarily vary in different cases. The Society of Apothecaries, of which he wished to speak with the greatest respect, had laid down an order of study which he thought was in some points inconvenient in practice. Thus they recommended that anatomy, physiology, and chemistry should be studied during the first year, but he thought that it was much better that the students should learn their anatomy and chemistry during the first year, and begin physiology in the second. With regard to examinations, he approved of a division and subdivision of the subjects, so that the student might pass from step to step, leaving some subjects behind him as he went on in his curriculum. In Scotland, the University Professors held class-examinations, which were very useful and formed part of the plan of education for the Medical Degrees; but in England, where the teachers and the examiners were distinct from one another, such a plan could not be carried out without great difficulty. In England annual class-examinations might be held, though not by the Medical teachers themselves; they might, however, arrange some plan of annual examination with the Medical Corporations, as the London College of Physicians, the College of Surgeons, and the Society of Apothecaries. With regard to the subjects taught, such extensive sciences as Chemistry should not be required to be learned in all its branches by the Medical candidate, but only such parts as bore upon medicine; and parts of the subject should be selected and placed in a programme, as in the University of London, which specified the portions of Chemistry in which it expected the Medical candidate to be prepared. The examinations of every kind should be practical, for he had found, in his experience as an examiner, that a candidate might pass an excellent written examination in anatomy, and afterwards be found entirely ignorant of anatomy on the dead body. Such a case had actually occurred to him when he was examining for the University of London. He thought, notwithstanding Mr. Syme's objections, that clinical examinations should be insisted on, not to prove that a candidate is an accomplished practitioner, but that he knows how to begin making a diagnosis; and such clinical examinations

* On a subsequent occasion, as will be seen by our report, Mr. Arnott offered some very judicious and sensible observations on the subject of Medical Education.

may be conducted without any danger or inconvenience to the patients. The examinations of all the corporate bodies should be subject to supervision on the part of the Medical Council, and the latter body should satisfy itself that the examinations were sufficient to test the competency of a candidate. The written portions of the examination should be submitted to supervision, particularly the papers of the lowest successful candidate and of the highest unsuccessful one, and the Council or its delegate should be present at the practical examination. With regard to the alleged excess of lectures, they have not been increased either in length or in number; and, in London at least, sufficient time is given to practical study. The excess of lectures is alleged by the idle portion of the students as a pretext for their inattention, but the industrious students willingly attend the lectures. One course of lectures, if duly attended, should be sufficient upon each subject, and attendance on subsequent courses ought to be optional. Class-examinations are found by Dr. Sharpey to be well attended at first, but after a time the attendance drops off, although these examinations are useful not only to those who are examined, but also to those who are listening to the others. But these examinations should be written as well as oral, so as to employ all the students at once, which cannot be done when the examination is only oral, and one person only can be examined at a time. Dr. Sharpey does not think that the division of the session into two portions of four months each can be conveniently adopted in London.

Dr. Storrar agreed in thinking that it was inexpedient to lay down uniform rules for all the examining bodies, and thought that a certain latitude should be allowed, and that the Licensing Bodies should fix their own curricula. The University of London, for instance, recommends a certain number of subjects of lecture, but leaves the student to select which he likes; but it insists upon a knowledge of practical anatomy and practical chemistry. Class-examinations are no doubt very useful as a part of the course of education; but they should not be allowed to supersede the final examinations. They might succeed in some of the Scotch Universities, where the professors and the examiners were the same persons; but they could not be successful in London, where a conflict might often ensue between the teachers of the schools and the Examining Boards.

Mr. Arnott observed that there were two methods of teaching Medicine and Surgery—namely, the professorial and the tutorial; and the former was almost exclusively adopted in the Scotch Universities, and was the oldest system; but the tutorial is now combined with it. He maintained that the object of all Medical Education should be to make men practitioners, and not merely theorists. He believed what Dr. Parkes had said was perfectly true as to the ignorance displayed, at the Examinations of the Army Board, by candidates who had already obtained diplomas and licences; but such candidates came from all parts of the United Kingdom, and not from any one part. (Dr. Parkes here remarked that no candidates had been rejected from Oxford and Cambridge, because no candidates had offered themselves from those institutions.) The essential ignorance displayed by candidates in the present day is not in doctrine, but in practice; and the question arose how this evil was to be remedied. The Examiners of the College of Surgeons laid great stress upon the importance of Hospital practice; but still they advocated attendance on lectures as an exceedingly useful mode of learning the Profession. But students had offered themselves for examination who never saw a case of operation for strangulated hernia, or of dislocation of the hip, or of acute retention of urine. Mr. Arnott then showed some statistical results obtained by the census returns, showing the number of patients on one given day in the Hospitals of Scotland, Ireland, and England—giving, as might be expected, a great preponderance in numbers in the English Hospitals; and out of 10,414 persons in Hospital in England and Wales, 4,000 were in the London Hospitals, leaving upwards of 6,000 in the provincial hospitals, excluding workhouses, which are, however, available for practical Medical instruction. Mr. Arnott proceeded to argue that the great Hospitals were not exclusively the schools for Medical instruction, which might be pursued with great advantage in the provinces and the country districts, and that students who had undergone a preparatory training of this kind were much better adapted for understanding Medicine and Surgery than those who had received no such instruction. This kind of preliminary Medical study might not, perhaps, be applicable to Scotland; but in England, students should be encouraged to attend country hospitals and workhouses, and the time so spent should be received as part of the curriculum. Even country practitioners who are not Hospital Surgeons may be very good instructors of youth, and in the course of general practice may give valuable instruction to their pupils. Mr. Arnott thought that Clinical examinations, although very desirable, were impracticable under existing circumstances.

Mr. Cooper thought that four years of professional study, instead of being too much, was too little. The Society of Apothecaries requires an apprenticeship, including the whole period of study, of five years; but the system of apprenticeship is valuable or otherwise according to the character, as to talent and reputation, of the person to whom the pupil is apprenticed. If the master is a gentleman and a scholar, well acquainted with his profession, and willing to afford instruction, the pupil possesses great advantages; and he has the opportunity of seeing a great number of cases both in Medicine and Surgery, and becomes acquainted with the uses and properties of drugs.

Dr. Alderson thought that public examinations were inexpedient, as they would have a tendency to embarrass the candidates; and, in some instances, where this plan had been tried, it had been abandoned. Besides, the Examinations of the Medical Corporations were, in some sense, public, as before the Fellows of the College of Physicians, who, however, delegated their powers to the President and Censors.

Dr. Corrigan expressed his intention to vote against both

the motion and the amendment. He objected to any attempt on the part of the Council to make a uniform curriculum, like the bed of Procrustes, and compel every one to accommodate himself to its requirements. The Council ought to endeavour to find out what a man's information is, and not how or where he acquired it. He asked whether the Regulations relating to preliminary education were really in force with all the licensing bodies? It was true, they were adopted in London, but not in the provinces or in Scotland and Ireland. (Here there were interruptions from Mr. Syme, Dr. Paget, and others, affirming that the corporate bodies with which they were connected had conformed to the Recommendations.) Dr. Corrigan, however, proceeded to read, from the Directory, extracts from the Regulations of several Examining Bodies declining to comply with the Recommendations—as, for instance, the Universities of Edinburgh and Glasgow, Aberdeen and St. Andrew's, the Faculty of Physicians and Surgeons of Glasgow, the Queen's University in Ireland, the College of Physicians in Ireland, the College of Surgeons in Ireland. Practical examinations ought to be insisted upon in all cases, in order to obviate the evils and deficiencies pointed out by Dr. Parkes and Dr. Sharpey. Dr. Corrigan believed that the reason why the corporations do not improve their examination is because one is afraid to overstep another. He saw no valid objection to practical examinations. He thought that the proposed scheme of the supervision of examinations on the part of the Council was impracticable, as it would be impossible to determine who was a competent person to determine upon the fairness, or the sufficiency, of the examination in any given case. Could he, for instance, determine whether Dr. Apjohn was a competent examiner in chemistry, or whether Mr. Arnott was a fair examiner in surgery? For these reasons, he thought the plan could not be carried out.

Mr. Hargrave defended the College of Surgeons in Ireland, in neglecting to comply with the recommendations relating to preliminary education, and stated that the College had been compelled to adopt that course by the acts of the Council itself, which had failed to make its recommendations compulsory.

This debate was resumed on Monday, and was continued all that day, the last speakers being the President and Mr. Syme. We regret that we are unable to print the speeches in full, although we have enlarged our Journal for the purpose. At the conclusion of the day's proceedings, however, the motion and the amendment were both lost, almost unanimously, Mr. Syme eventually voting against *his own motion!* Thus the whole question remains exactly where it did.

We cannot forbear from expressing our thanks for the courtesy and politeness shown by the officials of the Medical Council to the representatives of the Medical Press, to whom every accommodation is afforded in the exercise of their duties.

SUMMARY OF THE WEEK.

THE ADULTERATION OF OUR DAILY FOOD.

A paper has lately been read by a lady, at the Brighton Literary and Scientific Institution, on the practice of employing certain substitutes for the genuine ingredients in some articles of daily food, and on the effects of such practice on the health of the community. The remarks in the paper are in great measure directed against the use of certain substances which are very commonly employed by the public, especially the poor, as substitutes for some of the nutritious ingredients in bread, puddings, and pastry; and which, though not injurious to health, are not calculated to afford sustenance to the human body. The so-called "Baking Powder" is said to be composed of carbonate of soda and tartaric acid, combined with a small portion of rice or flour; and the "Egg Powders" as they are called, contain none of the nutritive properties of eggs, and are reported sometimes to be coloured with chromate of lead, and therefore to be positively objectionable. It is argued by the writer of the paper that if cooks are generally intrusted with such compounds, they will be induced to substitute them for the really nutritious articles of food, and thus to commit a fraud upon their employers; and that, moreover, they may thus occasionally introduce poisonous matters into the body. The remarks made by this lady are entitled to attention, especially by the female part of the community, to whom the preparation of our food is in great measure intrusted; and her earnest recommendation to all ladies, whatever their station, to superintend personally the operations of the *cuisine*, will, we hope, be extensively followed. If all ladies would study, practically or theoretically, the principles of cookery, much waste would be avoided and more health would be insured.

A LATE COURT-MEDICAL AT GREENWICH.

At the commencement of the present year a very disagreeable misunderstanding arose between two neighbouring Medical practitioners at Greenwich, Dr. Purvis and Dr. Moon, in consequence of some observations having been supposed to be made by the latter to the disparagement of the former gentleman. The case was referred to a Court-Medical, the result of which was that Dr. Moon exonerated himself from the charge of having made the observations attributed to him, and on a minor charge expressed his regret at an accidental omission made by him in a certificate of death. In some remarks we offered at the time, we expressed a hope that the two gentlemen in question would be reconciled and that the unpleasant affair would be forgotten. Such, however, we regret to find is not the case, for we have received a pamphlet entitled 'The Case stated between Dr. Moon and Dr. Purvis,' in which the former relates the whole of the proceedings from beginning to end, and again exonerates himself from the charge of endeavouring to disparage Dr. Purvis in the eyes of his patients. It appears to us that the real cause of offence given to Dr. Purvis was the transference of a patient under his care to that of Dr. Moon, together with the suspicion that he (Dr. Purvis) had been supplanted by unfair means. Such,

however, does not seem to have been the case, the change having arisen solely from the fancy, or the preference, or the caprice of the patient herself and her friends. We think it quite established that there was no neglect or malpraxis on the part of Dr. Purvis, and, on the other hand, that there was no underhand influence used by Dr. Moon against Dr. Purvis; and we again earnestly hope that the friends of both parties will endeavour to promote a reconciliation.

CHEMISTRY AT THE COLLEGE OF PHYSICIANS.

Having last week taken the College of Physicians to task for their atomic numbers, on the subject of the chlorides of mercury (p. 284), we feel bound to state, in justice to Dr. Frederic Farre, that the mistakes which we pointed out were due to an error on the part of the person who reported Dr. Farre's speech, and that this error is acknowledged by the journal which published the report. We make no apology for pointing out the error, which was a most important one in the present state of chemical science, but we believed it arose from a mistake of the reporter, which now turns out to be the case. If the College of Physicians allow unauthorised reports to appear, it is quite evident that it is impossible to prevent mistakes from occurring, and those mistakes from being commented upon and exposed.

THE COUNCIL EN SEANCE.

The Medical Council meets as heretofore, when assembled collectively, in the Library of the Royal College of Physicians, in Pall mall. The Members sit round an enormous circular table, each having before him a large pile of books and papers, and the President sits on an elevated seat at one point of the circumference. Next to him on his left sits the Registrar, Dr. Francis Hawkins, and next is the short-hand reporter employed by the Council. The Members of the Council sit in no particular order of precedence, but each appears to have his proper seat, probably chosen by himself. Neither nationalities nor collegiateties seem to influence the cohesive attraction or the repulsive powers of these representatives of the Medical Profession, for the Scotch and Irish Members are intermingled with the English without any apparent principle of selection. Nor do the sentiments expressed by the speakers indicate any of that feeling of nationality or clanship which might be anticipated; for the most vehement opponents to one another are sometimes Scotch against Scotch, and Irish against Irish. It is a curious fact, that although Scotland is the smallest and most thinly-peopled section of the United Kingdom, there is a numerical majority of Scotchmen on the Medical Council; not only the Scotch Corporations all sending (as might be expected) Scotch representatives, but the representatives of the University of London, and of the London College of Surgeons, and one of the English Crown nominees, being from the North. Out of twenty-four members of the Medical Council, in fact, nine are Scotchmen, and seven are Irish, leaving only eight Englishmen; and of the latter, whom we class as Englishmen, we are not quite sure that some may not be natives of Caledonia or of the Emerald Isle.

TRINITY COLLEGE *v.* THE KING AND QUEEN'S COLLEGE OF PHYSICIANS OF IRELAND.

On Tuesday, the 26th ult., the Master of the Rolls delivered judgment in the case of the Attorney-General at the relation of the Provost and Fellows of Trinity College, Dublin, *v.* the King and Queen's College of Physicians. The question involved, which was as to the right of the College of Physicians to grant the degree or title of Doctor of Medicine, was argued before his Honour in last Michaelmas Term, and turned mainly upon the construction of the College Charter granted in 1692. His Honour reviewed the arguments at great length, and said he was of opinion that the College of Physicians had no right to grant the degree of M.D., and that in so doing they had gone beyond the powers of their Charter. The College of Physicians in England were so far from seeking to usurp the power of granting such a degree, that they expressly prohibited their Licentiates from using the title of M.D., or any other title implying the possession of an University degree, unless they were in fact graduates of some University. The Act 23 and 24 Vic., cap. 66, authorised the Crown to grant a new Charter to the College of Physicians, and if the Fellows of the College were properly advised they would have applied for a new Charter, authorising them to confer degrees instead of usurping a power for which there was not a colour of foundation. The license which the College of Physicians were empowered to grant was a licence to practise physic; and the new Registry Act recognised the distinction between Doctors of Medicine and Licentiates. His Honour observed that so far from suggesting that there was any distinction in point of professional status between a physician who had obtained the University degree of M.D. and a Licentiate of the College of Physicians, he only expressed the general opinion of the public that both were equal—both stood equally high in public estimation. The judgment should be, therefore, in favour of the petition, and he would order the respondents to pay the Attorney-General his costs.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

MINUTES OF MEETING, MONDAY, APRIL 25, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Present—Dr. Burrows, President, in the chair; Dr. Alderson, Mr. Arnott, Mr. Cooper, Dr. Acland, Dr. Paget, Dr. Embleton, Dr. Storrar, Dr. Alexander Wood, Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Dr. Corrigan, Dr. Sharpey, Dr. Parkes, Dr. Quain, Mr. Rumsey, Dr. Christison, Dr. Stokes. Dr. Francis Hawkins, Registrar.

The Minutes of the last meeting were read and confirmed.

The following Committees were appointed:

Business Committee.—Dr. Andrew Wood, Chairman; Dr. Embleton, Dr. Corrigan, Mr. Rumsey.

Finance Committee.—Dr. Sharpey, Chairman; Mr. Arnott, Dr. Fleming, Dr. Aquilla Smith, Dr. Quain.

Committee on Returns received from the Bodies in Schedule (A).—Dr. Embleton, Chairman; Mr. Cooper, Dr. Thomson, Dr. Leet, Dr. Apjohn, Dr. Stokes.

1. Moved by Dr. Andrew Wood, and seconded by Dr. Alexander Wood: "That reporters be admitted to the meetings of the General Medical Council."

First amendment, moved by Dr. Acland, and seconded by Dr. Christison: "That a Committee be appointed to consider, and to report to the present meeting, the advantages and the disadvantages to the business of the Council which may arise from the admission of reporters; and to suggest the various ways in which (should the Council resolve to introduce them) they might be admitted to the Council, Branch Councils, or Committees."

Second amendment, moved by Dr. Thomson, and seconded by Mr. Cooper: "That the Council deem it expedient and desirable that their proceedings should be published, and that a Committee be forthwith appointed to consider and report upon the best means of accomplishing this object."

The second amendment was put to the vote, and the numbers were found to be equal for and against it.

The President then gave his casting vote in favour of the amendment.

Dr. Andrew Wood required that the names for and against the amendment should be taken down.—For the amendment: The President, Mr. Arnott, Mr. Cooper, Drs. Acland, Paget, Storrar, Thomson, Sharpey, Quain, Mr. Rumsey, Drs. Christison, Stokes. Against the amendment: Drs. Alderson, Embleton, Alexander Wood, Andrew Wood, Fleming, Mr. Syme, Dr. Smith, Mr. Hargrave, Drs. Leet, Apjohn, Corrigan, Parkes.

The following members of Council were appointed a Committee to consider and report as to the Best Mode of publishing the Proceedings of the Council—Dr. Thomson, Chairman; Mr. Cooper, Drs. Storrar, Alexander Wood, Apjohn, Corrigan, Mr. Rumsey, Dr. Stokes.

Moved by Dr. Alexander Wood; seconded by Dr. Stokes; and agreed to: "That the Committee appointed to Consider the Best Means of publishing the Proceedings of the Council be requested to report to-morrow; and that the consideration of that Report take precedence of all other business."

2. Moved by Dr. Quain; seconded by Dr. Andrew Wood; and agreed to: "That a Committee be appointed to revise the Standing Orders."

The Committee to consist of—Dr. Christison, Chairman; Drs. Storrar, Alexander Wood, Corrigan, Quain.

Confirmed, GEORGE BURROWS, President.

MINUTES OF MEETING, TUESDAY, APRIL 26, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. Burrows, President, in the chair.

The minutes of the last meeting were read and confirmed.

1. Dr. Thomson presented the following Report from the Committee appointed to consider the Best Means of publishing the Proceedings of the Council.

REPORT.

The Committee on Publication of the Proceedings of the Council met this day, and having considered the matter remitted to them by the Council, agreed by a majority to adopt the following resolutions, and directed the Chairman to lay these resolutions before the Council as the Report of the Committee:

1. That reporters be admitted to the meetings of the Council.
2. That a special reporter be engaged by the Council to prepare a report of the proceedings.
3. That the Council reserve the power of withholding the privilege of admission to the reporters whenever the Council may think fit.

ALLEN THOMSON, Chairman.

Moved by Dr. Thomson; seconded by Mr. Hargrave; and agreed to: "That the Report be received."

Moved by Dr. Thomson, and seconded by Dr. Stokes: "That the Report be adopted."

Amendment moved by Mr. Syme, and seconded by Dr. Andrew Wood: "That the Council proceed to consider the resolutions contained in the Report separately." The amendment was carried.

Moved by Mr. Syme, and seconded by Dr. Andrew Wood: "That the first resolution of the Report be adopted."

Amendment moved by Dr. Alderson, and seconded by Dr. Quain: "That the second resolution of the Report be first considered." The amendment was negatived. The motion was then put to the vote, and carried.

Moved by Dr. A. Smith; seconded by Mr. Arnott; and agreed to: "That the second resolution of the Report be adopted."

Moved by Dr. A. Smith; seconded by Mr. Arnott; and agreed to: "That the third resolution of the Report be adopted."

Moved by Dr. Parkes; seconded by Dr. Fleming; and agreed to: "That the Business Committee, with the President and the Registrar, be appointed a Committee to carry into effect the foregoing resolutions."

2. Dr. Christison presented the following Report of the Committee appointed to revise the Standing Orders:

REPORT.

The Standing Orders Committee appointed on the 25th instant to revise the Standing Orders of the Council report that they have for the present confined their attention to Articles 7, 8, 9, and 10 of Section III., "Order of Business." They recommend that these articles be repealed, and that the following be substituted:

1. That the seconder of a motion may, if he pleases, reserve his speech.
2. That if an amendment be proposed on a motion, the amendment shall be disposed of before any other amendment shall be moved.
3. That such amendment shall first be put to the vote; that if it be negatived, a second amendment may be moved, and shall be disposed in the same way as the first amendment; and so on until no further amendment shall be proposed.
4. That should every amendment be negatived, the original motion shall then be put to the vote.
5. That if any amendment be carried, it shall then be put as a substantive motion, and treated, as to further amendments, and the right of speaking on it, in all respects as an original motion.

Moved by Dr. Christison; seconded by Dr. Storrar; and agreed to: "That the Report be received."

Moved by Dr. Alexander Wood; seconded by Dr. Parkes; and agreed to: "That the resolutions of the Report of the Committee on Standing Orders be considered *seriatim*."

Moved by Dr. Alexander Wood; seconded by Mr. Arnott; and agreed to: "That the first resolution of the Report of the Committee on Standing Orders be adopted."

Moved by Mr. Arnott, and seconded by Dr. Storrar: "That the second resolution of the Report be adopted."

Amendment moved by Dr. Alexander Wood, and seconded by Mr. Syme: "That the present Standing Orders, in regard to the number of amendments that may be moved on any motion, be not altered." The amendment was negatived. The motion was then put to the vote, and carried.

Moved by Dr. Storrar; seconded by Mr. Arnott; and agreed to: "That the third resolution be adopted."

Moved by Dr. Storrar; seconded by Mr. Hargrave; and agreed to: "That the fourth resolution be adopted."

Moved by Mr. Hargrave; seconded by Mr. Arnott; and agreed to: "That the fifth resolution be adopted."

Moved by Mr. Arnott; seconded by Dr. Paget; and agreed to: "That the number of Members of the Executive Committee be confined to four, exclusive of the President."

Moved by Mr. Arnott; seconded by Mr. Syme; and agreed to: "That the Members of the Executive Committee shall be elected by ballot, by means of marked lists."

Moved by Dr. Andrew Wood; seconded by Dr. Embleton; and agreed to: "That the claims of Messrs. Spottiswoode, referred to the General Council by the Executive Committee, be now referred to the Finance Committee to be reported on by them."

Confirmed, GEORGE BURROWS, President.

MINUTES OF MEETING, WEDNESDAY, APRIL 27, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. Burrows, President, in the chair.

The Minutes of the last Meeting were read and confirmed.

1. Moved by Dr. Quain; seconded by Mr. Hargrave; and agreed to: "That a Committee be appointed to consider and report on the arrangements to be made for producing the next edition of the British Pharmacopœia."

The committee to consist of—Dr. Christison, Chairman; Dr. Acland, Dr. Alderson, Dr. Apjohn, Dr. Quain, Dr. A. Smith.

2. Moved by Dr. Storrar; seconded by Mr. Sharpey; and agreed to: "That the Council do now resolve itself into a Committee on Education."

3. Moved by Dr. Storrar; seconded by Dr. Alexander Wood; and agreed to: "That the President be requested to take the chair, and preside over the Committee."

1. Moved by Dr. Storrar, and seconded by Mr. Hargrave: "That the Committee proceed to consider, one by one, the recommendations of the Council, relating to General and Professional Education and Examination."

Amendment moved by Mr. Syme, and seconded by Dr. Andrew Wood: "That the Committee do now proceed

to consider the whole subject of Medical Education and Examination, with the view of preparing a Report for the guidance of Licensing Bodies." The amendment was negatived. The motion was then put to the vote and carried.

2. Moved by Dr. Storrar, and seconded by Dr. Sharpey: "That the first recommendation, viz.: 'That all students pass an examination in general education before they commence their professional studies,' be adopted."

Amendment moved by Dr. Acland, and seconded by Dr. Paget: "That the first resolution stand as follows:—'That all students pass an examination on subjects to be included under the head of general education prior to the date from which the commencement of their professional studies is to be reckoned.'" The amendment was negatived. The motion was then put to the vote and carried.

3. Moved by Dr. Storrar, and seconded by Dr. Sharpey: "That the second resolution be adopted, viz.: 'That the time of commencing professional studies shall be understood to be the time of commencing studies at a medical school; and that no qualifying body be held to have complied with the recommendation of the Council which shall allow the examination in general education to be passed after the commencement of professional study."

Amendment, moved by Mr. Arnott, and seconded by Dr. A. Smith: "That 'the time of commencing professional studies shall be understood to be the time of commencing studies at a medical school,' be transferred to the recommendations on professional education." The amendment was carried.

Amendment, moved by Mr. Arnott, and seconded by Dr. Acland: "That the concluding paragraph of the second recommendation, viz.: 'That no Qualifying Body be held to have complied with the recommendation of the Council which shall allow the examination in general education to be passed after the commencement of professional study,' be omitted." The amendment was carried.

Moved by Dr. Parkes, and seconded by Mr. Hargrave: "That testimonials of proficiency granted by the National Educational Bodies, according to the subjoined list, may be accepted, the Council reserving the right to add to, or take from, the list."

'1. A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council.
2. Oxford Responsions or Moderations.
3. Cambridge Previous Examinations.
4. Matriculation Examination of the University of London.
5. Oxford Middle Class Examinations (Senior).
6. Cambridge Middle Class Examinations (Senior).
7. Durham Middle Class Examinations (Senior).
8. Durham Examinations for Students in Arts, in their second and first years.
9. Durham Registration Examination for Medical Students.
10. Dublin University Entrance Examination.
11. Queen's University, Ireland, Two Years' Arts Course for the Diploma of Licentiate in Arts.
12. Preliminary Examinations at the end of A.B. Course.
13. Middle Class Examinations.
14. Matriculation Examinations.
15. First Class Certificate of the College of Preceptors.
16. "Testamur" granted by Codrington College, Barbadoes.
17. Degree of Associate of Arts granted by the Tasmanian Council of Education, with a Certificate that the Student has been examined in Latin and Mathematics.'

Amendment, moved by Dr. Corrigan, and seconded by Mr. Rumsey: "That testimonials of proficiency granted by the National Educational Bodies, according to the list contained in the third recommendation, be accepted, provided that the Examinations conducted by those Bodies comprise at least the following subjects:—English, Greek, Latin, Mathematics, Arithmetic to the end of Decimal Fractions, One Modern Language." The amendment was negatived.

Amendment moved by Dr. Alexander Wood, and seconded by Dr. Andrew Wood: "That a Minimum Standard of Preliminary Education and Examination shall be fixed by the Council; that testimonials of proficiency granted by the National Educational Bodies may be admitted, provided the Council deem the education required by them to be sufficient; and that a Sub-Committee be appointed, to prepare the Minimum Standard to be submitted to the Council for its consideration."

At six o'clock, the Meeting of the General Committee was adjourned.

Confirmed, GEORGE BURROWS, President.

MINUTES OF MEETING, THURSDAY, APRIL 28, 1864.
ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. Burrows, President, in the Chair.

The minutes of the last Meeting were read and confirmed.

1. Moved by Dr. Storrar; seconded by Mr. Hargrave; and agreed to: "That the Council do now resolve itself into a Committee on Education."

---

1. The Committee resumed the consideration of the amendment moved, at the last Meeting, by Dr. Alexander Wood, and seconded by Dr. Andrew Wood, viz.: "That a Minimum Standard of Preliminary Examination shall be fixed by the Council; that Testimonials of Proficiency granted by the National Educational Bodies may be admitted, provided the Council deem the education required by them to be sufficient; and that a Sub-Committee be appointed, to prepare a Minimum Standard to be submitted to the Council for its consideration." The amendment was negatived.

The original motion, moved, at the last Meeting, by Dr. Parkes, and seconded by Mr. Hargrave, was then put to the vote, and carried, viz.: "That Testimonials of Proficiency granted by the National Educational Bodies, according to the subjoined List, may be accepted, the Council reserving the right to add to, or take from, the List:—

1. A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council.
2. Oxford Responsions or Moderations.
3. Cambridge Previous Examinations.
4. Matriculation Examination of the University of London.
5. Oxford Middle Class Examinations (Senior).
6. Cambridge Middle Class Examinations (Senior).
7. Durham Middle Class Examinations (Senior).
8. Durham Examinations for Students in Arts, in their second and first years.
9. Durham Registration Examination for Medical Students.
10. Dublin University Entrance Examination.
11. Queen's University, Ireland, Two Years' Arts Course for the Diploma of Licentiate in Arts.
12. Preliminary Examinations at the end of A.B. Course.
13. Middle Class Examinations.
14. Matriculation Examinations.
15. First Class Certificate of the College of Preceptors.
16. 'Testamur' granted by Codrington College, Barbadoes.
17. Degree of Associate of Arts granted by the Tasmanian Council of Education, with a Certificate that the Student has been examined in Latin and Mathematics."

2. Moved by Dr. Storrar, and seconded by Mr. Arnott: "That the Fourth Recommendation of the Council be adopted, viz.: 'That the Examination in General Education be eventually left entirely to the Examining Boards of the National Educational Bodies recognised by the Medical Council.'"

Amendment moved by Dr. Stokes, and seconded by Mr.

Syme: "That with the view of saving time, a Sub-Committee be appointed, for the purpose of preparing a Report on the subject of Medical Education, which may form a definite basis for the discussions of the question in the General Council." The amendment was negatived. The motion was then put to the vote, and carried.

3. Moved by Dr. Storrar, and seconded by Dr. Sharpey: "That the Fifth Recommendation of the Council be adopted, viz: 'That no Certificate of Proficiency in General Education, which does not affirm the Proficiency of the Candidate in Latin, be deemed a sufficient proof of Preliminary Education previous to the commencement of Professional Studies.'"

Amendment moved by Dr. Corrigan, and seconded by Dr. Apjohn: "That no Certificate of Proficiency in General Education, which does not affirm an acquaintance with Greek and Latin, be deemed a sufficient proof of Preliminary Education previous to the commencement of Professional Studies." The amendment was negatived. The motion was then put to the vote, and carried.

4. Moved by Dr. Storrar, and seconded by Dr. Sharpey: "That the Sixth Recommendation be adopted, viz.: 'That Students who cannot produce any of the Testimonials referred to in the Third Resolution, be required to pass an Examination in Arts, established by any of the Bodies named in Schedule (A) of the Medical Act, and approved by the General Council, provided that such Examination be in every case conducted by a Special Board of Examiners in Arts.'"

Amendment moved by Dr. Corrigan, and seconded by Mr. Hargrave: "That the words after 'General Council,' in the fifth line of the Sixth Recommendation, be omitted; and that the Recommendation be adopted as thus amended."

The amendment was carried.

5. Moved by Dr. Storrar, and seconded by Dr. Sharpey: "That the Seventh Recommendation be adopted, viz.: 'That without professing to lay down any complete scheme of General Education for persons intending to become Members of the Medical Profession, the Committee recommend that the Scheme of Examination in Arts of the Licensing Bodies be, as nearly as practicable, similar to that of any of the National Educational Bodies above specified.'"

This motion was put to the vote, and negatived.

6. Moved by Dr. Storrar; seconded by Dr. Embleton; and agreed to: "That the Eighth Recommendation be adopted as follows: 'That all Medical Students be required to be registered.'"

7. Moved by Dr. Storrar; seconded by Dr. A. Smith; and agreed to: "That the Ninth Recommendation be adopted, viz.: 'That the Lists of Students registered be closed within fifteen days after the commencement of each Session or Term.'"

8. Moved by Dr. Storrar; and seconded by Dr. A. Smith: "That the Tenth Recommendation be adopted, viz.: 'That no Student beginning Professional Study after September, 1861, be registered, who has not passed an Arts Examination, in conformity with Resolutions 3 or 6.'"

Amendment, moved by Dr. Alexander Wood, and seconded by Dr. Acland: "That a Sub-Committee be appointed to consider the best Scheme of Registering Medical Students."

The amendment was carried, and the following Committee appointed: Dr. Alexander Wood, Chairman; Mr. Arnott, Dr. Embleton, Dr. Fleming, Dr. Apjohn, Dr. Stokes.

Confirmed, GEORGE BURROWS, President.

MINUTES OF MEETING, FRIDAY, APRIL 29, 1864.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Dr. Burrows, President, in the chair.

The Minutes of the last meeting were read and confirmed.

1. An application having been made to the Medical Council to recognise the Entrance or Matriculation Examination of the Catholic University in Ireland, it was moved by Dr. Christison; seconded by Dr. Storrar; and agreed to: "That the following answer be returned by the Registrar, to the communication now before the Council:

"'SIR,—I have laid before the General Medical Council your letter of the 18th inst., requesting that the Entrance Examination of "The Catholic University of Ireland" should be recognised among the Examinations in Preliminary Education received from the various chartered or incorporated Educational Bodies; and in reply I am directed to request you will have the kindness to transmit to the General Medical Council a copy of the Charter or Act of Incorporation of the "Catholic University."'"

2. Dr. Christison presented the following Report of the Committee appointed on the 28th April, 1864, relative to the 'Pharmacopœia':

REPORT.

The Committee report—

1. That it is desirable to make further arrangements during the present Session of Council, for preparing the next edition of the 'British Pharmacopœia.'
2. That a Committee of the Council be appointed to superintend the preparing for the press, and the editing of the work, and to submit the same to the Council for approval, in proof.
3. That the gentlemen already nominated in London, Edinburgh, and Dublin, for the purpose of reporting from time to time on the improvements in Pharmacy, be requested to continue their services, and that their report be communicated to the Pharmacopœia Committee of the Council.
4. That an Editor or Editors shall be appointed by the Pharmacopœia Committee, who shall prepare the work, in all its details, under their control.

Moved by Dr. Storrar; seconded by Dr. Christison; and agreed to: "That the Report of the Committee, relative to the 'Pharmacopœia,' be received and entered on the Minutes."

3. Moved by Dr. Andrew Wood; seconded by Mr. Hargrave; and agreed to: "That the Council resolve itself into a Committee on Education, and that the President be requested to take the chair."

1. Dr. Alexander Wood presented the following Report from the Sub-Committee on the best scheme of Registering Medical Students:

REPORT OF THE SUB-COMMITTEE ON REGISTRATION OF MEDICAL STUDENTS.

Your Sub-Committee is of opinion that the Registration of Medical Students, if properly conducted, is a matter of primary importance, as giving security to the Council and the Profession—

1. That every Student has passed an Examination in Arts before commencing his Professional Studies.
2. That the exact date at which a Student has commenced his Professional Studies has been ascertained and registered, so as to show how far the Recommendations of the Council in these respects have been complied with.

The chief difficulties which past experience has shown to exist appear to your Committee to be—

1. The want of a sufficient distinction between Students commencing their Studies and those who may be commencing their second, third, or fourth Sessions.
2. The fact that many Students enter at several different Schools at the same time.

Having regard to these difficulties, your Sub-Committee begs to recommend the following Regulations, as at once simple and practical:

1. That the Registration be placed under the charge of the Branch Registrars.
2. That each Student be only once registered, and that when he first enrols himself as a Medical Student.
3. That the Registrar of each School of Medicine, or other authorised person, keep a List of all Students entering for the first time at that School, agreeably to the subjoined Form.
4. That the Register at each School be closed within Fifteen Days after the commencement of each Session or Term.
5. That these Lists, as soon as possible thereafter, be transmitted, along with the Certificates of each

Student having passed an Arts Examination, to the Branch Registrar of that division of the Kingdom where the School is situated, and that he from them frame an accurate Register of Medical Students of that division of the Kingdom where he has charge.

6. That the Register of Medical Students so prepared by the Registrars, after examination by the several Branch Councils, be transmitted to the Registrar of the General Council, who shall, under direction of the Executive Committee, print the same in alphabetical order, and supply a copy of this Authorised List to each of the Bodies in Schedule (A) to the Medical Act.
7. That the several Licensing Bodies be requested, after October 1868, to abstain from examining any Candidate for License or Degree whose name does not appear on the Authorised List of Medical Students.
8. That the Branch Councils be desired to take means to make these regulations known to the Medical Students at the various Medical Schools.

ALEXANDER WOOD, Chairman.

Moved by Dr. Andrew Wood; seconded by Dr. Embleton; and agreed to: "That the Report of the Sub-Committee on Registration of Medical Students be received and entered on the Minutes."

Moved by Dr. Andrew Wood; seconded by Dr. Embleton; and agreed to: "That the Consideration of the Report on the Registration of Medical Students be deferred till after the Discussion of the question of Professional Education."

2. Moved by Dr. Storrar, and seconded by Dr. Paget: "That the Seventeenth Recommendation of the Council be adopted, viz.: 'That the age of Twenty-one be the earliest age at which any Professional Licence shall be obtained.'"

Amendment, moved by Mr. Syme, and seconded by Dr. Andrew Wood: "That the Committee proceed to consider the Subjects and Course of Study requisite for a Medical Professional Education."

The amendment was carried.

3. Moved by Mr. Syme, and seconded by Dr. Andrew Wood: "That the Council proceed to frame a Course of Study for Medical Education, which may be recommended to the Licensing Bodies."

The debate on this subject not being concluded at six o'clock, it was moved by Dr. Thomson; seconded by Dr. Parkes; and agreed to: "That the Committee do now adjourn."

OBITUARY.

DR. ROBERT MAYNE, F.K. AND Q.C.P.

We announce with sincere regret, in which a large circle will participate, the death of this eminent physician, which took place on Thursday, April 7, at his residence, Upper Gloucester street. For many years he was one of the medical attendants of the South Dublin Union, where he had great opportunities of studying disease in all its phases, and acquiring that knowledge and extended experience which had raised him, at a comparatively early age, to a foremost rank in his profession. On resigning this post he was appointed physician to the Adelaide Hospital, where he zealously laboured up to the day his fatal illness began, and deservedly gained the esteem of both pupils and patients by a manner of unvarying kindness. He was ever ready to impart instruction to those who sought it from him, and by none will his death be more lamented than by the students who had the benefit of his valuable teaching. Dr. Mayne was also Lecturer on the Practice of Physic in the Carmichael School of Medicine, Physician to the General Post-office, and President of the Pathological Society. Twelve days ago he was struck down by a bad attack of typhus fever—a disease of which he had a presentiment he would die—and sank on Thursday morning at five o'clock. When it is stated that he was under the care of Drs. Stokes, Corrigan, M'Dowel, and Kirkpatrick, it will be known that everything that medical skill could accomplish was done to avert what all will regard as a serious loss. In a word, the Medical Profession has lost one of its noblest members. We understand that the remains of the lamented gentlemen were removed on the following Saturday, at half-past eight o'clock, for interment in Mount Jerome.

DEATHS.

BOLLAND.—On the 25th ult., at Gardiner's place, Dublin, John Bolland, L.R.C.P.Ed., of Daventry, Northamptonshire, aged 26.

HAMILTON.—On the 21st ult., at Prince's road, Liverpool, R. Hamilton, Surgeon, aged 78.

KELLY.—On the 1st ult., at Pembroke street, Liverpool, J. Kelly, M.D., aged 70.

MATHER.—On the 20th ult., H. Mather, C.M., of Earlestown, Newton-in-Mackerfield, Lancashire.

M'GILL.—On the 21st ult., at Tonbridge, W. M'Gill, M.D., aged 51.

PARETT.—On the 13th of March, J. Parett, M.R.C.S.E., of Dover.

MARSLAND.—On the 12th ult., Martha, the wife of Robert Marsland, M.R.C.S., Manchester, aged 36.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 26th inst.:—Frederick Henry Appleby, East Retford, Notts; George Benson Baker, Southport, Lancashire; Thomas Bond, North Petherton, Somerset; Edgar Athelstone Browne, Notting hill; Alexander Bruce, Albert terrace, Regent's park; Wm. Boyle Coghlan, M.A., Queen's Univ. Ireland, Manchester; John Reuben Bathurst Dove, Falfield, Berkeley, Gloucestershire; John Frederick Foster, Guernsey; Henry William Freeman, Bideford, Devon; Robert Chapman Gibson, Fyfield, Ongar, Essex; Henry George Benvenuto Harris, Coombe Down, Somerset; John William Hayward, Seasalter, Kent; Nynian Holman Lower, Lewes, Sussex; Edward M'Conkey M'Cready, M.B., Trinity College, Dublin, Birmingham; Robert Morris Meiklejohn, Bombay; Alexander Clement Rayner, Bedford; Edward Peter Shorland, L.S.A., Westbury, Wiltshire; Joseph Bower Siddall, L.S.A., Morton, Derbyshire; Thomas Haywood Smith, Alcester, Warwickshire; John Sidney Turner, Seaford, Sussex; Henry Viant, Totton, near Southampton; Albert James Wallis, Cambridge.

The following were admitted Members on the 27th inst.:—Charles Adcock, Birmingham; William Bullus, West Bromwich; Laurence Corban, Cork; Henry Couling, Kingston Bagpuize; Charles Davidson, Orkney; Alfred Ensor, Dorchester; Thomas Henry Green, Saffron Walden; Richard Wheeler Haynes, L.S.A. Bromsgrove; John Henry Hughes, M.D., Queen's University, Ireland, Armagh; George Vincent Langworthy, Modbury, Devon; Charles Frederick Long, L.S.A., Ipswich; William George Vawdrey Lush, L.S.A., Wilton, near Salisbury; William M'Candlish, Glasgow; Edward Maundrell, Calne, Wiltshire; George Henry Madeley, Kensington; Thomas Robert Nason, Nuneaton; John Powdrell, L.S.A., Farndon; Comberbach Reade, Congleton; John Henry Salter, Arundel; Spencer Henry Simpson, Stowmarket; Joseph Snape, Liverpool; Ebenezer Snell, Plymouth; James Walbridge Snook, Wellington, Shropshire; William Spooner, Southampton; Allen Wearing, Lancaster; William Yates, Richmond.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 21st inst.:—John William Devereux Bain, Brunswick terrace, Blackwall; John Edward Gunning, Surbiton, Surrey; Richard Istance, Carmarthen; Joseph Carter Neynoe Murphy, 75th Regiment.

UNIVERSITY OF ABERDEEN.—At the late graduation

term, the following candidates, after the usual examinations, received degrees in Medicine and Surgery:—Degree of M.D.—Samuel Davidson, M.A., Wartle, Rayne, George Dickson, L.R.C.P. & S., Edinburgh, William Gregory Van Dort, Colombo, Ceylon, John Gray M'Kendrick, Aberdeen, honourably distinguished; James Copland, M.A. (Ed.), Edinburgh; John Dunlop, L.R.C.P. & S. (Ed.), Lanarkshire; John Fraser Grantown; William Grant, Methlic; James Foote Henderson, Aberdeen; James Ledingham, M.A., Aberdeen; William James Smith, Kintore; George Charles Henry Wigan, M.R.C.S.E., L.A.C., Bristol; George Yeats, Aberdeen.

At the same time the following gentlemen were promoted to the degree of M.D.:—James Ross, M.B. (H. Hon.), and M.C. (H. Hon.), Aberdeen; James Clark, M.B., Aberdeen;

Degree of M.B.—Geo. M'Iver Campbell, M.A., Old Aberdeen, Robt. Alex. Farquharson, M.A., Ballater, honourably distinguished; George Andrew, M.A., Huntly; Theunis Johannes Botha, Cape of Good Hope; Charles Burnett, Alton, Hants; Stewartson Clark, New Pitsligo; Alexander Duncan, M.A., Aberdeen; James Hector, Aberdeen; Robert Keith, Keith hall; Robert Davidson Kemp, Aberdeen; Godfrey Alexander Macrae, North Uist; Alexander Minty, Kennethmont; John Murray, Woodside; William Paterson, M.A., Aberdeen; Peter Shepherd, Leochel-Cushnie; William Henry Stewart, Grantown; Thomas Watt, M.A., Aberdeen.

Degree of M.C.—Robert Alexander Farquharson (highest honours); George M'Iver Campbell, Samuel Davidson, William Gregory Van Dort, John Gray M'Kendrick, William Paterson, honourably distinguished; George Andrew; Theunis Johannes Botha; Charles Burnett; Stewartson Clark; James Copland; John Fraser; William Grant; John Gray; James Hector; James Foote Henderson; Robert Keith; Robert Davidson Kemp; James Ledingham; Godfrey Alexander Macrae; Alexander Minty; John Murray; Peter Shepherd; William James Smith; William Henry Stewart; Thomas Watt; George Charles Henry Wigan; George Yeats.

At the same time the following were declared to have passed part of their examinations:—William Scott Aitken; Frederick P. Atkinson; Alexander Campbell; John M. Campbell; William Duncan; Owen Evans; George Findlay; James E. Fowler; William Robert Gordon; Alex. Lyall Grant; James Grant; Edward Gray; Alfred Orlando Jones; George King; John Knox; John Macpherson; Josiah W. Matthews; John S. M'Gowan; Robert Moir Milne; Alex. Gordon Mitchell; Edwin B. Muskett; David Nicolson; Archibald G. Robertson; John Robson; James Rodger; Robert John Scott; Robert Shiels; John Simpson; Alex. B. Strahan; Charles James Trenerry; John Whyte; Alfred Harold Wheldon; James Williamson.

COURSE OF LECTURES ON THE HISTORY OF MEDICINE AT PARIS.—Dr. Daremberg gave, on the 18th instant, the first lecture of this course, and will continue it twice a week. The lectures are delivered at the College of France, the State institution of Paris for the cultivation of the higher branches of science.

NEW YORK SANITARY FAIR.—A fair has been opened at New York in aid of the funds of the Sanitary Commission of that place. It is to be kept open for a month, and is expected to realise two millions of dollars. It is to be hoped that the funds will be applied to the purposes for which they are to be ostensibly raised.

THE FOSSIL ELEPHANT OF MALTA.—More remains of this animal have been discovered by Dr. Leith Adams, F.G.S., in extensive excavations lately made by that gentleman among the cavern deposits and breccias near Crendi. One of the chief points with reference to the fossil elephant found in Malta is the small size of its teeth, which, coupled with other characteristics, leaves no doubt that it was not only distinct from any living or extinct species, but was, as regards dimensions, a pigmy compared with them. It is supposed not to have been larger than a lion. Such relics, together with the bones and teeth of hippopotami, &c., which of late years have been met with in great abundance in different parts of Malta and Gozo, tend to show that these islands are but fragments of what may at one time have been an extensive continent, in all probability connected with either Europe or Africa, or both. At all events, the physical geography of this portion of the Mediterranean must have changed very much since the above-mentioned animals wandered over our islands. To those who take an interest in the wonderful discoveries made by geologists of late years, it is worthy of notice that teeth and bones of the living elephant of Africa, and another larger fossil species, together with the hippopotamus, have been lately discovered by Baron Anca in the Palermo caves, thus showing that in all probability no less than three distinct descriptions of elephants, and two species of hippopotami, frequented an area embraced within the southern point of Sicily and Malta, and during the post-pliocene period, when we find the earliest traces of man's existence. None of the latter have yet been met with in Malta. But there is every probability that flint implements and such like will turn up, as they have done in the Sicilian caves, more especially now that the attention of scientific inquirers has been earnestly directed to this important subject. Without the invaluable testimony afforded by the remains of the quadrupeds above-mentioned, there are downcast fragments of the strata and faults along the shores of Malta, which testify to the submergence of the land. Besides, the subaqueous plateau, named Adventure Bank, uniting Sicily to Africa by a succession of ridges not more than 40 to 50 fathoms under water, points to the former contiguity of that island and the continent of Africa. So marked is the latter, that Sir C. Lyell has asserted that Sicily might be re-united to Africa by movements of upheaval not greater than those which are already known to have taken place within the human period in Sardinia, where the bed of the sea has been elevated 300 feet since man inhabited that island.—'Malta Times,' March 31.

KEEPING A CORPSE UNBURIED,—On Saturday last (the 23rd inst.) Mr. Godrich, the Medical Officer of Health for Kensington, applied to Mr. Dayman, the police magistrate, for powers to compel the burial of a man who had died a fortnight previously, and whose friends refused the assistance of the parish in his burial. The case was the more important as the house in which the corpse lay was crowded with occupants. Mr. Dayman said that he had no power to interfere. The only remedy would be by indictment. Such a state of the law demands attention.

SANITARY REFORM IN INDIA.—Letters received by the last Calcutta Mail state that the Bengal Government is taking active measures to abolish the native custom of throwing the bodies of the dead into the River Ganges, and of burning dead bodies at the Mintollah burning ghât, whence the sickening fumes are wafted over the city of Calcutta. These reforms have raised a storm of opposition, amongst the Hindoos. The correspondent of the 'Times writes:—"In other respects judicious endeavours are being made to purify the capital. The health officer has been making a 'hygienic survey' of the town—a thing hitherto unheard of. The filthiness of this place, the loathsome stench that fills nearly every street, the utter neglect of cleanliness and decency among the native population surpass belief. The only mystery is that Europeans are able to live here at all. The city is ten times as dirty as the bazaars at Cairo, and smells fifty times nastier than Cologne. There is likely at last to be an improvement in it; but the co-operation of the natives ought to have been secured in the first instance, instead of their opposition being aroused."

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAY 4.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Hunterian Society, 8 p.m.—Mr. Couper, "On a Case of Vertical Dislocation of the Patella."

THURSDAY, MAY 5.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; Great Northern Hospital, King's cross, 2 p.m.; London Sur-

gical Home, 2 p.m ; West London Hospital, 2 p.m. ; Royal Orthopædic Hospital, 2 p.m. ; Royal Institution, 3 p.m.—Mr. Hullah "On Music (1600—1750)" ; Chemical Society, 8 p.m.—Sir B. C. Brodie, "On the Organic Peroxides Theoretically Considered ;" Harveian Society, 8 p.m.—Dr. Sisson, "On the Origin and Nature of Syphilis."

FRIDAY, MAY 6.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m. ; Royal Institution, 8 p.m.—Prof. Roscoe, "On Indium, &c."

SATURDAY, MAY 7.—*Operations* at St. Thomas's Hospital, 1 p.m. ; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m. ; St. Bartholomew's Hospital, 1½ p.m. ; King's College Hospital, 1½ p.m. ; Royal Free Hospital, 1½ p.m. ; Charing-cross Hospital, 2 p.m. ; Royal Institution, 3 p.m.—Prof. Frankland, "On Metallic Elements."

MONDAY, MAY 9.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m. ; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAY 10.—*Operations* at Guy's Hospital, 1½ p.m. ; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Prescriber's Pharmacopœia. By a Practising Physician. Fifth Edition. London: John Churchill and Sons.

Fifth Annual Report of the Sussex County Lunatic Asylum, Hayward's heath.

A Voice from Derby to Bedlam. London: R. Hardwicke, 192 Piccadilly.

The Dental Review. No. II. New series.

Transactions of the Obstetrical Society of London for the year 1863. Vol. V.

A Brief Topographical and Historical Notice of Calcutta ; with a Sketch of the Rise and Progress of Sanitary Improvement in the East Indies. By Sir J. R. Martin, F.R.S.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

D. G. H.—The letter is inserted.

THE ROYAL INSTITUTION.—The notice has been received.

DR. M. will find that the subject has been noticed.

ALPHA.—We cannot suggest or recommend any form of public advertisement for the purpose alluded to ; but the object might be gained by making the proposed change known to private friends and acquaintances, or to patients, which would be a strictly legitimate and proper course.

WE have received the extracts from the 'Dublin Evening Post,' and the able and elaborate letter which accompanies them ; but we are disposed, on legal grounds, to coincide in the decision given by the Master of the Rolls.

THE OBSTETRICAL SOCIETY.—The notice has been received.

MR. T. M. D., *Dublin*, is thanked for his communication.

IN consequence of the length of our Report of the Proceedings of the Medical Council, we are compelled to omit a communication "On the Diseases of the Heart," by Dr. Semple.

INSPECTOR-GENERAL DOLMAGE'S paper has been received, and will be published immediately.

SUBSCRIBER.—It has been maintained that pus was the result of the liquefaction or saponification of the disintegrated tissues when the acid products were brought into contact with them ; it is, however, really a degeneration of lymph.

DUM SPIRO, SPERO.—A registered practitioner without a diploma is not eligible to hold a Poor-law appointment. A pure physician cannot recover, in England or Ireland, for medicines supplied to his patient. The above answers are the best we can give to the imperfect questions asked. We do not precisely understand the supposed case of a registered practitioner without a diploma.

THE Report of the Harveian Society will be inserted next week.

Apothecaries' Hall.—The next Examination in Arts will be held at the Hall on Friday and Saturday, the 23rd and 24th September, 1864. A Syllabus of the Subjects for Examination may be had on application.

An examination will again be held in the month of January, 1865.

R. B. UPTON, Clerk to the Society.

DINNEFORD'S

Pure Fluid Magnesia, now perfect in purity and strength.

"Mr. Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d. ; gallon, 9s. 6d.,) specially adapted for the use of Medical Men and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London ; all Wholesale Druggists and Patent Medicine Houses.

Mr. Howard, Surgeon Dentist,

52 FLEET STREET.

has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble natural teeth as not to be distinguished from the original by the closest observer, they will never CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does NOT REQUIRE the EXTRACTION of ROOTS, or any PAINFUL OPERATION, and will support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication. Decayed teeth stopped and rendered sound and useful in mastication.—52 FLEET STREET. At home from Ten till Five.

MINERAL WATERS IN A PORTABLE FORM.

Savory and Moore have prepared in a GRANULAR and EFFERVESCENT Condition the Constituent of the following MINERAL SPRINGS :—

VICHY SALT—CARLSBAD SALT—PULLNA SALT—SELTZER SALT—FACHINGEN SALT—KISSENGEN SALT—MARIENBAD SALT—CHELTENHAM SALT, &c., &c., &c.

PORTABLE AND ECONOMICAL SUBSTITUTES FOR LITHIA WATER :—

GRANULATED AND EFFERVESCING CITRATE AND CARBONATE OF LITHIA.

TONIC AND FEBRIFUGE PREPARATIONS :—

GRANULATED AND EFFERVESCING CITRATE OF IRON AND QUININE.

GRANULATED AND EFFERVESCING CITRATE OF QUININE.

GRANULAR EFFERVESCING AMMONIO-CITRATE OF IRON.

Savory and Moore beg to announce that, in addition to the above, they are now manufacturing on a large scale all the GRANULATED MEDICINES in use, such as—

CITRATE OF MAGNESIA—CITRO-TARTRATE OF SODA—CARBONATE OF IRON PURIFIED TAR—GREGORY'S POWDER—DR. BELLOC'S CHARCOAL, &c., &c.

AGENTS FOR MR. LIGHTFOOT'S MAGNETIC SOLUTION OF PHOSPHATE OF IRON MR. SCHACHT'S FLUID PREPARATION OF BISMUTH.

143, NEW BOND STREET, LONDON.

Weiss's Illustrated Catalogue, con- taining nearly 800 Engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price 5s.

62 Strand, London.

"This Catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced ; and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour, which we are glad to see strictly observed in this Catalogue."—Vide 'TheLancet,' Sept 12th, 1863.

James's Fever Powder, 4s. 6d. per bottle ; packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all wholesale Druggists.

T. & H. Smith's Codeia Lozenges. These Lozenges have a remarkable effect in allaying COUGH, and IRRITATION of the THROAT and CHEST.

Prepared only by T. and H. SMITH and Co., 21, Duke Street, Edinburgh ; and 69, Coleman Street, London ; in Boxes at 1s. 1½d. and 2s. 9d. each.

Medical Fixtures and Glass Manu- FACTORY, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of HOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

BY J. LUMLEY EARLE, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 276.)

The Preventive Treatment.

Prec. 13.—Having found the uterus contracted, and any clots obstructing the os being removed, a pad, made by folding up two or three napkins, should be placed partly over and partly above the fundus of the uterus, and the binder again pinned tightly. While the placenta was *in utero*, the bandage acted sufficiently alone as a stimulant, but not so when the placenta has been removed; the uterus is now small, and therefore, in order to apply direct pressure to that organ, it becomes necessary to add the pad. If, instead of finding the uterus contracted, it feel large and soft, the binder ought not to be tightened; as, in the case of an uncontracted uterus, there is no safeguard equal to the hand, which should be kept on the uterus until due contraction sets in, and then, and not until then, ought we to relinquish the pressure of the hand for that of the binder.

Prec. 14.—As is well known, the late Dr. Rigby recommended the application of the child to the breast soon after delivery as a means of preventing post-partum hæmorrhage. I have tried this plan, and found it answered in some cases, while it failed in others. In order to apply the child to the breast, the mother is obliged to make some exertion, for the breast has to be exposed; then this plan fails very often, because the child will not or cannot suckle. The new-born infant is sometimes disinclined to suckle immediately after its birth, or it cannot do so from the mother having a small or flat nipple, or from some fault on its own side, as cleft palate or tied tongue, for example. The mother, in her anxiety to make the child take the breast, moves herself, thinking that perhaps her position is awkward to the infant, or she pulls the child to her, and tries by every means in her power to make it take hold of the nipple. These movements of the patient are liable to place her in danger, and I have seen one or two instances of flooding after labour, the cause of which I could not attribute to anything else but the exertion made by the mother in the often fruitless attempts to get the child to suckle. For the above reasons, I have for some time discontinued the application of the child to the breast as unsatisfactory.

In its place, however, I substitute, in cases where the uterus seems disinclined to contract, a plan which is exactly the same in principle, has all the advantages, without any of its disadvantages. It consists of compression of the breast with the hand. If we place one hand upon the uterus, while we grasp the breast with the other, the uterus will be felt to contract almost instantaneously. As the patient lies on her left side, the hand should be passed under the axilla of her right arm; the hand will then come at once upon the breast. Gentle compression or squeezing of the breast should be employed at regular intervals. Latterly, I have somewhat modified the mode of exciting sympathy between the breast and uterus. Instead of squeezing the breast, I imitate the sucking action of an infant by placing the thumb and index finger on each side of the nipple, about an inch and a half or two inches from each other, and then I draw them forward just in the same way as if I were desirous of drawing a little milk to the apex of the nipple for microscopical examination in a case of suspected pregnancy, only the action must be much quicker, and repeated frequently. As a preventive means, there is no necessity for the medical attendant to use this precaution himself. The nurse should be shown how to manage it. She merely has to pass her hand under the axilla of the arm of the patient, feel for the nipple outside the chemise, and use the thumb and finger as described. In some cases when I am going to remove the placenta, I direct the nurse to place her left hand upon the breast, and the right hand on the uterus, and press them both at the same time, while I remove the placenta. It assists in insuring a firm contraction of the uterus.

The irritation of the mamma with the hand is preferable to the application of the child to the breast, for the following reasons: 1. It insures perfect rest to the mother. 2. It can be kept up for any length of time. 3. There is no chance of failure in its application. It is not requisite to employ this precaution in every instance; only in those cases where the uterus feels flabby, and there is great difficulty in stimulating it to contract. Before leaving the house, if I have any apprehensions of hæmorrhage commencing after my departure, I give the nurse directions to continue its employment for some considerable time.

Prec. 15.—The medical attendant ought not to leave the house until an hour has elapsed since the delivery. If the patient should go on for an hour without flooding, with proper care there is not much likelihood of serious hæmorrhage occurring afterwards. A large number of cases might be, and are left a short time after delivery without any harm arising, but it is very unsafe to do so. Some of the most experienced writers on midwifery emphatically recommend this precaution. Gooch may be mentioned especially, as he took great interest in the subject of post-partum hæmorrhage. As Dr. Arthur Farre used to say, in his admirable lectures at King's College: "If you stay with your patients an hour after their delivery, you will very rarely be called back again; if you don't, you may lose a patient from flooding." I very nearly lost two cases in consequence of my having left soon after the delivery of the placenta. The following are the notes of one of the cases: When resident accoucheur to the Dispensary, I attended, one Sunday morning, five cases of labour. Having finished three of them, I went to the fourth, and found that the child was already born, and the placenta expelled. There had been pretty free loss of blood, but not then sufficient to produce apparently any effect upon the constitution. I was very anxious to go to the fifth; and as the uterus seemed pretty well contracted, and the discharge moderate, I bound the patient up and left. The fifth case had been over some time, so I had not to wait with her long. I had not been home twenty minutes, and was dressing myself, when the midwifery bell was rung violently. The servant came to say that the husband of one of the patients confined that morning wanted me to go with him immediately, as he thought his wife was dying. I went down to the man, and found that he was the husband of the fourth case. "Oh, sir," exclaimed he, "come directly; my wife is speechless." I told him to get a cab, and by the time it had arrived I was dressed and ready. During the drive down, he told me that his wife could not speak. I then asked him whether she had had any brandy given to her. He said that there were three or four women in the room, but he had not seen them give her anything. I confess my fears were, that she would be dead before I could get to her assistance; fortunately, the terror-stricken attendants had called in a neighbour, who had seen two or three cases of flooding treated, and she administered brandy freely. On my arrival, the patient had slightly rallied. The uterus was large and blood was flowing away freely. I saw at once that her state would not allow the throwing away of time by trying simple remedies, therefore I passed my hand into the uterus and removed a quantity of clots, and then following up with pressure, cold, and ergot, the hæmorrhage was arrested. She remained in a very critical condition for many hours, requiring brandy every few minutes to keep her from fainting, but she slowly recovered.

No doubt some who may read this paper will say, "It is

very true that it is safer not to leave a patient until she has been delivered an hour, but I have so large a practice that I cannot spare the time." If labours usually terminated in the day time, a medical man in large practice could not well spare the time. The majority of cases, however, terminate either before the work of the day is begun, or after it is finished; it is quite the exception for labours to terminate during the hours of the day in which patients come to see us, or we can go and see them. If a medical man, even with a large midwifery practice, were to note down the number of hours he had lost during *the hours of work* in a year, from remaining with his patients the required time after delivery, I expect he would find it to be ridiculously small. I feel convinced that if we wish to do justice to our patients, and practise midwifery satisfactorily, we must not omit this precaution, if possible.

Prec. 16.—When the patient has been confined an hour, and there is no hæmorrhage, she may have the wet things removed, including the binder, which is generally soiled at its lower edge, and the clean things drawn down. Gooch recommends us not to move the patient for two hours. This advice is very good; but the reason I do not follow it in ordinary cases is, because I do not feel satisfied unless I ascertain the condition of the patient *after* she has been placed in bed, and I prefer applying the binder myself. It is important to feel the state of the uterus and ascertain the amount of discharge after the patient has "been put to rights," as the pulling off the wet clothes and drawing her higher up in the bed is sometimes quite sufficient to bring on flooding. Amongst the poor, most of whom, if allowed, will be confined in their stays and numberless petticoats, it is not uncommon for hæmorrhage to set in after they have been undressed and placed in bed. The greater the difficulty in removing the clothes, of course, the more the mother has to exert herself, and the more liable is she to flood. Directions should be given to the nurse to move the patient as little as possible, and not to let her sit up for one moment. The wet things should be drawn away gently, and then the clean things drawn down. All these points can be effected much more easily and with more safety by two than by one; it is as well, therefore, to have another woman to assist the nurse. When the patient has been placed comfortably in bed, the medical attendant should examine the pulse, and pass his hand over the uterus to feel whether it be of proper size and contracted; and the patient should be asked whether she feels much loss. These three points being satisfactory, a good wide calico binder should be passed under the hollow of the back, and with the assistance of the nurse drawn under her, so that the lower edge of the binder extends down to the trochanter major. Two napkins should be placed over the fundus of the uterus, and then the binder pinned tightly on the right side of the patient.

What I have to say of the binder I shall say now, as it should be only used as a means of preventing, not arresting hæmorrhage. No one in his right senses would make use of a binder while hæmorrhage was going on. The binder acts like an artificial hand, applying pressure and irritating the uterus into a permanent and equable contraction. It is a safeguard which no prudent practitioner would think of omitting. Besides the binder, the application of a pad over and above the fundus of the uterus is of great value. The binder applies equable pressure over the abdomen, whereas the pad applies direct pressure to the uterus. The pad I use in ordinary cases, where there has been no hæmorrhage, consists merely of two thick napkins—one-half placed over, the other half above the fundus. If there has been flooding, a safer pad consists in rolling up three big napkins separately—one should be placed transversely above the fundus; the other two perpendicularly, one at each side of the uterus. The upper extremities of the side pads should lie over those of the upper pad. In this way the uterus becomes enclosed, as it were, in a box; and if the binder be tightened firmly over them, it is almost impossible for the uterus to escape from their clutch. About twenty years ago a very animated discussion arose, I think in the pages of the 'Lancet,' on the subject of applying a binder after delivery. A few contended not only that it did no good, but actually did harm. One objected to it on the ground that it was liable to bruise the uterus. Without a pad I believe it would be very difficult to bruise the uterus, let the bandage be applied ever so tightly. We must remember that the uterus is a movable organ, and on that account the actual compression is not so great as it would appear to be. The uterus is pressed downwards and backwards. If the uterus were immovable, it would be easy to understand how bruising of its structure could be produced by a tight binder. Another gentleman gave it as his opinion, that the binder is a prolific source of *prolapsus uteri*. That would be very difficult to prove, and it seems rather curious, that the very application, which generally gives such relief in prolapse of the uterus, should be one of the causes of that distressing malady.

One of the best proofs to my mind of good accruing from the application of a binder, is the comfort it affords to the patient. They generally tell you "How nice that feels!" "Oh, how beautiful!" and other like exclamations.

Dr. Tyler Smith states, in his 'Manual of Obstetrics,' that he has known cases where he had been obliged to attribute a fatal result from hæmorrhage to the neglect of applying a binder after delivery. I can quite credit it, and I am very glad to find that this eminent and practical authority so strongly recommends its application.

HOSPITAL REPORTS.

KING'S COLLEGE.

On Saturday, April 22nd, Mr. Fergusson operated for nævus, on a young child of about twelve months old. The nævus was situated on the centre of the right cheek, and presented a very unsightly tumour.

Arming a curved sharp-edged, as well as sharp-pointed, needle with a stout ligature, Mr. Fergusson passed it underneath the nævus, entering it on the outer side, and then bringing it through at the inner or nasal aspect. The loop of the ligature being then divided, and the needle withdrawn, one of the free ends was again passed from below upwards by means of the same needle, and the cheek was thus transfixed completely underneath the nævus, and in two directions—that is, from without inwards, and from below upwards.

The adjacent free ends of the ligatures are to be tied; but before this is done, the intervening integument must be cut. These were, therefore, the next steps of the operation. The ligatures were tied as tightly as they could be, so that the strangulation of the nævus was complete.

The second case upon which Mr. Fergusson operated was one that we mentioned before in some of our former hospital reports. The history is as follows:—Some years since, an ulcer appeared upon the inner side of the palm of the hand; this, which resisted all kinds of treatment, was considered by Mr. Fergusson to be malignant, the only contraindications to such a diagnosis being the rarity of that form of disease in so young a subject, and especially in the situation which this occupied. In our former notes of this case, we gave Mr. Fergusson's predictions, and to-day we had an opportunity of seeing them verified.

Entering the point of the knife at the inner side of the ulcer, and sweeping it down toward the base of the hand, and up again to the fissure between the forefinger and thumb, and then round upon the back of the hand, so as to separate the integuments from the metatarsal bones, at a point below their centre, the whole of the lower extremity of the hand was circumscribed by the line of incision. The integument on the dorsum of the hand was next dissected

up, and as the bones offered too great resistance to be cut through with the bone pliers, the saw was applied, first, to the metatarsal bone of the forefinger, which having been sawn across from its radial to its ulnar edge, the other bones of the metatarsus were then dealt with in the same manner. Hæmorrhage was prevented by compression of the radial and ulnar arteries, and was so completely arrested by Mr. Henry Smith, who undertook the office of compression, that scarcely a drachm of blood was lost in the entire operation. A number of vessels having been tied, the wound was immediately brought together by thread sutures. The inner angle of the wound was brought into nice apposition by means of a hare-lip needle and the twisted suture.

The peculiarity of this case was, that the woman was seven months advanced in pregnancy: this, however, Mr. Fergusson considered to be no objection to the operation, since the chances of non-contamination of the system by the cancerous poison were very much against the patient, if such a long period as that necessary for the accomplishment of her full time were allowed to pass without any operative procedures. The rapidity of growth manifested in the malignant disease led to the inference that, were the hand left to itself, the cancerous matter would have quickly extended upwards along the lymphatics and absorbents of the fore and upper arm, until at length the glands in the axilla would have been involved.

Mr. Wood then operated on two young men, both of whom were affected with scrotal hernia of the oblique form; they were young, strong, in full health, and the first patient was particularly muscular. The hernia in the second was of such a nature that it might be termed the false direct; it was really an oblique inguinal, but had existed for so long a time as to have the appearance of a direct inguinal hernia.

The steps of the operations were as follows:—The patient having been brought fully under the influence of chloroform, so that all the tissues might be relaxed as much as possible, and the tumour having been reduced completely, the pubis and groin of the side upon which the hernia lay were shaved; the penis was turned away to the sound side; and the scrotum being rendered tense by an assistant, Mr. Wood made an incision of about half or three-quarters of an inch long into its walls. This extended only beneath the tegumental portion of the scrotum. The blade of the knife was then passed into this incision between the fascia and the integument, and being placed horizontally and flatwise, was made to sweep round the opening for a distance of about two inches; this being the usual extent unless the tumour is very large. In order the better to separate the tissues from each other, the handle of the knife was now carried round the area which had been before cleared by the blade. The operator stood on the right side of the patient, that being the side on which the rupture had occurred; the forefinger had been introduced into the ring and canal prior to the operation, so as to ascertain beyond doubt that the hernia had been slipped back entirely, and also to explore the condition of the rings and of the canal.

When the protruded bowel does not come down any farther than the groin, and forms, in fact, a bubonocele, the incision in the scrotum should be commenced at an inch and a half below the pubal spine; if it be a large scrotal rupture, the line of incision running downwards and outwards must be made over the fundus of the sac.

The incision having been thus made, and the scrotal tissues separated in the manner above described, the knees of the patient were bent up towards the abdomen at the same time that they were approximated; by this means the parts were all relaxed, and manipulation rendered more easy. The forefinger of the right hand was now passed into the opening in the scrotum, and its nail being turned backwards it was forced up into the canal, pushing before it the fascia loosened from the other structures composing the scrotum; in its passage the finger lay between the sac in front and the spermatic cord posteriorly, which it thus protected from any danger of being wounded. Dipping the finger towards the cavity of the abdomen, and then again bringing it prominently forward, the lower border of the internal oblique was raised upon it; this step of the procedure was facilitated by gentle pressure upon the groin by means of the unemployed hand. The position of the inferior margin of the conjoined tendons was also ascertained. The curved needle was passed by the left hand along the forefinger of the right already introduced into the canal as far up as possible, and having resting upon it the edge of the obliquus internus; the needle was then driven through the internal pillar of the external ring in a direction upwards and inwards, the structures around being all the time protected by the forefinger; the integument was drawn somewhat tensely upwards and to the opposite side, so that the needle traversed it the more readily.

The wire, which was to be used for the bringing together of the hernial channel, and which had been prepared by having a half-loop made at each extremity, was passed through the eye of the needle and then quickly drawn through by a jerk of the operator's hand; one end of the wire was now through the scrotal aperture, and the other lay toward the abdominal puncture. The forefinger of the right hand was again introduced, and this time underneath the external pillar of the ring, as near to the internal ring as could be reached, and in the groove formed in Poupart's ligament by the cord lying upon it; through this structure the needle is now pushed and brought out through the same puncture in the skin as was first made; it is again armed with the other extremity of the wire and withdrawn, leaving the loop of the wire above at the abdominal puncture. When these steps have been accomplished, the needle, armed by one of the free ends of the wire, is passed through the sac of the hernia that it also may be taken up to form a component part of the new wall of the canal, and so afford a better security against a return of the protrusion.

The great principle of the operation, as Mr. Wood explained, is to effect a closure, not of the external or superficial ring alone, but of the entire canal; and, in order that this may be fully carried out, it is necessary for the sac to be traversed in three directions, that, being so traversed, it may be puckered up so as to form a kind of plug at the exit of the hernia, at the same time that the walls of the hernial channel are drawn tightly together. If the sac is merely pushed into the abdomen and the walls of the inguinal canal are then closed, we may have a protrusion existing at the deeper ring, and this bubonocele may at any time work its way down till it frustrates the object for which the operation was designed; but by treating the sac as well as the walls of the canal in the manner done by Mr. Wood, this danger of failure is obviated. In *recent* cases, however, we may push the sac back into the abdomen and retain it there by approximating the margins of the canal. This Mr. Wood has done in some of his cases, and with good results.

It is quite a fallacy to suppose that peritonitis is so readily induced as has been supposed, and even when it is set up, the form which it assumes is not the diffusive, but the limited, being confined to the parts immediately concerned in the operation. When, however, inflammation proves fatal, the cause will be found in the involving of the omentum or of the intestine, or of both.

The needle must be stiff and resisting, and have a short curve; it must not be too slender or it will yield. In bringing it out through the integument after having traversed the internal and external pillars of the canal, it is necessary that there be but the one point of exit; otherwise there will be a needless amount of integument constringed by the loop of the wire, there will be more suppuration, and a larger ulcer than should exist if there was only the one aperture. The advantage of having an opening in the scrotum is that any matter formed, owing to the irritation of the foreign bodies—wires, or threads, or needles, &c.—can find a ready exit.

In the case of children, needles are employed, not with the object of promoting suppuration, but rather to obtain merely the adhesive inflammation and an effusion of plasma.

In taking up the internal pillar of the ring or the inguinal canal, there is no danger of wounding the epigastric

vessels unless too great a sweep of the needle is made, and the tissues are perforated too close to the median line; nor is there any danger of wounding the vessels coursing in the direction of Poupart's ligament, when that structure is taken up by the needle.

The sac having been included in a loop of the ligature, the operation is completed by twisting upon itself each extremity of the wire—that is, the loop above and the free ends below; by this twisting the walls of the canal are brought together, while the external ring is plugged up by the sac. The wire is then curved over the bridge of integument lying between the opening in the scrotum below and the puncture in the abdomen above, and is further secured by passing the free ends through the loop to which then they are made fast, a piece of soft lint being placed on the subjacent integument, lest it should be injured by the wire; a perinæal bandage is swathed over the whole, and thus all danger of displacement is obviated. There was a peculiarity in the second case which did not exist in the first: it was, that the testicle on the side of the rupture was atrophied.

Mr. Wood had met such a condition in other cases, and had found the organ to assume its wonted dimensions when the cause of its wasting had been removed.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XIV.

AMMONIÆ CARBONAS.—This salt is described in the Materia Medica as "Sesquicarbonate of Ammonia," and formula $2\ NH_4\ O,\ 3\ CO_2$ is given to represent its composition. It will be observed, however, that its officinal name is simply carbonate of ammonia; the prefix "sesqui," which formed part of the name in previous Pharmacopœias, is now omitted.

Sesquicarbonate of ammonia is manufactured commercially by submitting to sublimation a mixture of crude muriate or sulphate of ammonia and chalk. The operation is generally conducted in iron vessels or retorts, which are heated by a furnace, and the carbonate as it sublimes is conveyed into leaden chambers, where it condenses. The salt thus obtained is never pure, and is therefore refined by a second sublimation. This is effected in iron pots, set in the flue of the furnace, and surmounted by leaden hoods. When the mixture of chloride of ammonium and carbonate of lime is submitted to heat, the reaction occurs:

$$3\ (Ca\ O,\ CO_2) + 3\ NH_4\ Cl = 3\ Ca\ Cl + (2\ NH_4\ O,\ 3\ CO_2) + NH_3 + HO.$$

The atom of ammonia and the water volatilizes at the commencement of the process, and the salt afterwards distils over.

No less than twelve different carbonates of ammonia have been described by chemists. Of these, however, several only differ from each other in the proportion of water they contain, and others are of little importance. The following, however, have some practical and theoretical interest:—

Monocarbonate . . .	$NH_3\ CO_2$
Hydrated carbonate . .	$2\ (NH_3\ CO_2)\ HO$
$\frac{5}{4}$ Carbonate . . .	$4\ NH_4\ O,\ HO,\ 5\ CO_2$
Sesquicarbonate . . .	$2\ NH_4\ O,\ 3\ CO_2$
Bicarbonate . . .	$NH_4\ O,\ HO,\ 2\ CO_2$.

It has been often urged as an objection to the ammonium theory, that the monocarbonate of ammonia cannot be represented in accordance with it. All attempts to produce a salt which should have the composition $NH_4\ O,\ CO_2$ have failed. The bicarbonate, however, may fairly be regarded as containing ammonium. Only two of the above salts are perfectly stable and uniform in their composition—namely, the monocarbonate and the bicarbonate. Professor Rose has therefore suggested that the intermediate salts may be only secondary combinations, and should be considered as double salts. According to this view, the sesquicarbonate of the $\frac{5}{4}$ carbonate would be represented thus:—

$\frac{5}{4}$ Carbonate . .	$3\ NH_3\ CO_2 + NH_4\ O,\ HO,\ 2\ CO_2$.
Sesquicarbonate .	$NH_3\ CO_2 + NH_4\ O,\ HO,\ 2\ CO_2$.

There are many facts which support this view of the composition of sesquicarbonate of ammonia. Thus, the pungent odour of the salt is due to the escape from it of the compound $NH_3\ CO_2$. It is well known that, by exposure to the air, the sesquicarbonate crumbles down to a white odourless powder; this substance is bicarbonate of ammonia, having the composition $NH_4\ O,\ HO,\ 2\ CO_2$. The salt thus spontaneously splits up into the two compounds of which it is composed. Mr. Scanlan has also shown that when sesquicarbonate of ammonia is treated with a small quantity of cold water, a solution of the monocarbonate is obtained; while a mass of bicarbonate, having the form and dimensions of the sesquicarbonate employed, and of which it is the mere skeleton, is left. Rectified spirit effects a similar but more complete separation. Moreover, sesquicarbonate of ammonia cannot be resublimed without undergoing a change in its composition. On the first application of the heat, pure carbonic acid escapes, and a portion of the hydrated monocarbonate sublimes; hence the resublimed sesquicarbonate of commerce generally contains some of the $\frac{5}{4}$ carbonate. It is on this principle that some of the best varieties of smelling salts are prepared. It is an objection to the use of simple sesquicarbonate for this purpose, that the monocarbonate it contains soon evaporates, and leaves a mass of odourless bicarbonate in the bottle. Various means have been resorted to, therefore, for increasing the proportion of monocarbonate in the salt. One of the most elegant of these consists in resubliming the sesquicarbonate in such a manner as to collect, separately, that portion of the sublimate which consists principally of $\frac{5}{4}$ carbonate. The impurities likely to be present in sesquicarbonate of ammonia are empyreumatic matter, hyposulphite of ammonia, sulphates, chlorides, lead, and lime salts. The empyreumatic matter comes from the employment of imperfectly purified sal-ammoniac in the prepara-

tion of the salt. Its presence communicates a tinge of colour to the solution, and also imparts an objectionable odour. The hyposulphite generally occurs when the carbonate has been made from sulphate of ammonia, or sal-ammoniac containing sulphate. The salt, when neutralized with acetic acid, gives a white precipitate with nitrate of silver, which rapidly turns black. The sulphates and chlorides may be recognised by supersaturating the carbonate with dilute nitric acid and testing the solution with nitrate of silver and chloride of barium. The lead is derived from the leaden receivers into which the salt is sublimed; it may be detected by sulphuretted hydrogen. The lime and other fixed impurities remain when the salt is volatilized.

Ammoniæ Hydrochloras.—There is an obvious inconsistency between the name and the formula given for this salt in the Pharmacopœia. The composition of the salt is represented in the Materia Medica by the formula $N H_4 Cl$, but this formula indicates chloride of ammonium and not hydrochlorate of ammonia. The latter name implies that the salt is composed of hydrochloric acid and ammonia; its formula should therefore be $N H_3, H Cl$. The symbols $N H_4 Cl$, on the contrary, represent this salt as constituted of chlorine and ammonium. The compilers of the Pharmacopœia have, in fact, constructed the name according to one theory and the formula according to another.

Sal-ammoniac is, at the present time, principally manufactured from the ammoniacal liquor of gas works. This liquid contains several salts of ammonia, but principally carbonate of ammonia and sulphide of ammonium. It is also contaminated with tarry matter, &c., and is a very offensive substance. Several processes are adopted for obtaining from it the ammoniacal salt. Sometimes it is saturated with sulphuric acid, the gases which are liberated, principally carbonic acid and sulphuretted hydrogen, being carried through a furnace. The solution of sulphate of ammonia so obtained is evaporated until the salt crystallises out. The brown crystals of sulphate of ammonia so obtained are mixed with common salt, and the mixture submitted to sublimation in iron pots. A double decomposition occurs, whereby chloride of ammonium is formed, which sublimes—

$$N H_4 O, S O_3 + Na Cl = N H_4 Cl + Na O S O_3$$

In some cases, the gas liquor is neutralised directly by hydrochloric acid, and the sal-ammoniac crystallised out. It is then partly purified from the tarry matter with which it is contaminated by torrefying it at a gentle heat. The tar is thereby rendered insoluble, and the salt can be purified by re-crystallisation; it is then, lastly, sublimed. Sometimes the hydrochloric acid is replaced by a waste liquor from salt works, which contains chloride of calcium mixed with chlorides of sodium and magnesium; carbonate of lime is precipitated, and sal-ammoniac remains in solution. In some manufactories the gas liquor is filtered through a stratum of powdered gypsum (sulphate of lime), whereby carbonate of lime and sulphate of ammonia are obtained.

The most frequent impurity of chloride of ammonium is iron, which is very difficult to separate.

REVIEW OF THE PERIODICALS.

The 'Journal of Practical Medicine and Surgery.'

Practical Remarks on Tracheotomy.

Like venesection, tracheotomy is an operation every practitioner should be always ready to perform, and the rules by which he must be guided should always be present in his mind. We, therefore, reproduce the remarks of Mr. Giraldès on this most important subject.

This surgeon, in the first place, is not partial to the use of numerous instruments, and rejects as unnecessary the greater part of those which have been specially invented to facilitate the performance of tracheotomy; the dilator and canula, against which a Professor of the School of Medicine recently inveighed at the Academy, appear to him, however, absolutely indispensable. Mr. Giraldès uses a convex and pointed blade for the performance of the necessary incision of the integument and puncture of the trachea, and a probe-pointed knife for the enlargement *upwards* of the aperture of that tube. Blunt hooks are also required to part the lips of the division. The dilator preferred by Mr. Giraldès is the three-bladed spring instrument, which is extremely handy. This appliance, invented by Mr. Laborde, is more convenient than the two-bladed dilator in previous use; when the latter has been adopted, the canula not unfrequently slips between the blades, and instead of entering the trachea, may glide into the cellular tissue. To avert this contingency, Mr. Laborde added a third blade, grooved on its upper surface, which acts as a conductor, and safely guides the metallic tube to its destination. The canula should always be double, and, if possible, moveable, like that constructed by Mr. Lüer, in order to prevent the occurrence of ulceration, and should be provided with a square piece of gummed silk, for the protection of the wound. A scovel completes the apparatus necessary for tracheotomy.

The following points require attention—viz., 1, The attitude of the patient and the position of the assistants; 2, The incision of the skin and soft parts; 3, The exploration and puncture of the trachea; 4, The introduction of the dilator and canula; 5, The means best calculated to prevent or check the primary accidents consequent on the operation.

The attitude of the child and the position of the assistants are important preliminaries, on which Mr. Giraldès dwelt at some length. The easy performance of the whole procedure altogether depends on the entire immobility of the patient. The subject should lie at full length on a mattress placed on a table, the head well thrown back, and the neck resting on a solid block, so as to bring forward the cricoid cartilage as the apex of the cervical region. An assistant, placed behind the child, should firmly secure the head in this attitude, with both hands applied to the jaws. A second assistant takes charge of the shoulders to avoid lateral displacement of the body and any oscillation of the trachea, the effect of which might be that the knife would enter the air-tube side-ways, and expose the patient to emphysema, and the surgeon to miss the trachea, two equally unfortunate contingencies.

Mr. Giraldès does not cause a fold of the skin to be raised in order to perform the incision, but after having ascertained with the finger the precise situation of the cricoid cartilage; he makes his division exactly in the middle line, below the cricoid, in an extent of nearly one inch. This incision, rapidly performed, should include the skin and subjacent cellular layer; a second sweep of the knife divides the aponeurosis and the intermuscular space, down to the thyroid gland.

Surgeons, in general, are inclined to make the incision longer, in order better to expose the parts; but Mr. Giraldès condemns this practice, because by lengthening the wound downwards, the operator wanders to a region gradually more distant from the trachea, and incurs the risk of injuring a greater number of superficial blood-vessels. Another disadvantage of an extensive wound is, that diphtheria may be propagated to its surface, and give rise to exhausting suppuration; an incision of ten or twelve lines is, therefore, amply sufficient.

The third stage of the operation requires the utmost coolness and self-possession on the part of the surgeon ; if any blood should escape, the source of the hæmorrhage must be discovered at once, and the bleeding checked. While the nail of the left forefinger fixes the trachea, the point of the knife, held like a pen in the right hand, is then pushed along the nail into the air-tube, and the penetration of the bistoury is indicated by a characteristic souud caused by the escape of air. The finger must not yet be removed, but the closed dilator should be introduced before proceeding to the fourth stage, viz., the dilatation of the artificial aperture and the insertion of the canula.

The forceps should not be held like a pair of scissors, because the hand has more tendency to close than to open ; the instrument should be held in the palm, and a slight motion of the fingers readily effects its dilatation, when a gush of fluid, mixed with false membranes, escapes from the trachea. The child should then be placed in a sitting attitude, in order to facilitate respiration and the expulsion of the false membranes, and of the blood, which may have trickled down into the air-passages. The canula may now be inserted.

When the division of the trachea is too small to admit the metallic tube, it should be enlarged at its *superior* angle. It is unnecessary to perform a large aperture; indeed, this practice is rather injurious than the reverse, and if the wound is somewhat too small, the circumstance can easily be remedied.

The accidents which may occur during the performance of tracheotomy are hæmorrhage and emphysema. On the present occasion we shall not advert to secondary complications.

The hæmorrhage may proceed from veins or arteries injured by a too hasty or too extensive incision, or in consequence of some anomaly in the situation of the arterial blood-vessels.

In general the bleeding ceases as soon as respiration is freely re-established. In the contrary case, rounds of agaric, impregnated with compound tincture of benzoin (*Baume du commandeur*), should be applied to check the hæmorrhage. If blood mixed with air gushes from the orifice of the canula, the inference is that the aperture of the trachea is too wide, and a larger canula should be inserted, exactly adapted to the size of the incision.

Emphysema of the neck is not a very frequent nor a very formidable complication. It is always the result of a laborious operation, in which the division of the skin and the puncture of the trachea are not exactly opposite each other. Whatever the cause, gentle pressure will in almost every instance remove the infiltrated air.

Careful after-treatment is necessary. We have on other occasions sufficiently dwelt on the subject; in the present remarks our object is merely to advert to the operative procedure. We may, in addition, without travelling out of the record, state that, in its execution, tracheotomy is perhaps the most unequable of surgical processes. In one patient it is performed with rapid brilliancy, in another it presents the greatest and most unexpected difficulties. If the phenomena of asphyxia are severe, death may even take place before the conclusion of the operation; in this case, however, death may only be apparent, and the child may sometimes be restored by assiduous frictions with ammonia over the chest and back, methodical manipulation of the thorax, insufflations, and electricity. Mr. Giraldès recommends one conductor to be applied along the course of the phrenic nerve, where it runs beneath the crossing of the omo-hyoideus and sterno-mastoideus muscles, and the other to the costal insertions of the diaphragm.

Avulsion of the Fore-arm in an attempt to reduce a Dislocation of the Shoulder.

Mr. A. Guérin, Surgeon to the Hospital Saint-Louis, recently witnessed an accident, probably unprecedented in scientific records, in the case of an old woman in whom he attempted the reduction of a dislocation of the shoulder of three months' standing. Every practitioner is aware that violent tractions, performed for the purpose of reducing old luxations, occasionally cause fracture of the bones or lacerations of the skin and muscles; these, however, are but partial disruptions. Such injuries have frequently occurred, and occasion no surprise ; but in the present case, the particulars of which Mr. Guérin candidly laid before the Society of Surgery, an entire limb was detached from the body under the influence of far less powerful efforts than are daily used for the reduction of recent dislocations.

The following is a brief abstract of the case:—Three months since, a healthy woman of sixty-three, who had never suffered from any disease beyond one attack of cerebral congestion which induced incomplete and transient hemeplegia, fell in a staircase and dislocated her left shoulder. A physician, summoned directly after the occurrence of the accident, mistook its nature, and treated the patient for contusion. Despite her sufferings, and the paralysis of the entire limb which supervened shortly afterwards, the woman remained in the same condition for six weeks, when unavailing efforts at reduction were instituted. Six weeks again elapsed without change ; she was then admitted into Mr. Guérin's ward at Hospital Saint-Louis, and the existence of complete dislocation of the humerus inwards and upwards beneath the coracoid process was clearly ascertained. On the 10th of March Mr. Guérin endeavoured to effect reduction in the usual manner. The patient was laid on a bed and chloroform was exhibited so as to induce muscular relaxation ; a sheet folded lengthwise was passed around the chest, its middle being close under the injured part, and its ends secured by an assistant standing on the opposite side ; another cloth, fixed to the wrist, was entrusted to four assistants. In the first tractive efforts the wrist-bands slipped, and were more firmly attached ; gradual extension was then instituted by four persons with a moderate amount of force. As the sheet again became displaced, it was supported with the hands of one of the students. While extension was progressing, suddenly, without any warning sound, without any elongation, or any circumstance whatever calculated to awaken attention, the limb gave way at the elbow, the forearm fell on the floor at the feet of the dismayed assistants, and a torrent of blood escaped from the wound ; the artery was at once secured, two inches and a quarter of the os humeri were excised, and the flaps were rendered regular. The total avulsion had been instantaneous, and yet the assistants had preserved their equilibrium.

Dissection of the parts fully accounted for this very extraordinary mischance ; the bones, muscles, nerves, bloodvessels, in short, every one of the tissues of the extremity, had undergone material alteration. The bony structure had become porous in its entire extent, and the interstices were filled with a brownish substance. The muscles, especially the pronator quadratus, and the lumbricales, presented the aspect of a red pulp. The nerves and bloodvessels had likewise suffered much change : the skin alone preserved an appearance of integrity, which concealed the morbid condition of the subjacent organs, and fatally misled the surgeon. These various anatomical changes were attributed by Mr. Guérin to the pressure exercised by the head of the humerus on the plexus brachialis, and lessen the regret which might otherwise be felt at this accidental amputation.

Messrs. Larrey, Houel, Voillemeir, Verneuil, and Broca took share in the debate which followed the recital of this extraordinary occurrence. The only question that gave rise to controversy was the morbid physiology of the case, and the Society unanimously agreed that the anatomical changes fully accounted for the disruption of the limb, and completely exonerated the operator from all blame. Mr. Broca clearly pointed out the practical inferences drawn from the event. "The case is a very serious one," said Mr. Broca ; "we must not forget it ; but I do not think it should create anxiety in the treatment of luxations. It is a mischance, and may possibly never occur again. I therefore persist in my belief in the perfect propriety of attempting the reduction of dislocations of long standing."

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 26.

Dr. BASHAM, Vice-President, in the Chair.

A paper, by Dr. MORELL MACKENZIE, was read, entitled

A DESCRIPTION OF THE FIRST LARYNGOSCOPE, AS INVENTED AND EMPLOYED BY DR. B. G. BABINGTON, F.R.S., IN THE YEAR 1829.

The author stated that in this communication it was not intended to trace the successive steps which finally led to the more general use of the laryngoscope in practical medicine. This had already been done in an able article by Mr. Windsor, in the 'British and Foreign Medico-Chirurgical Review.' The object of the present paper was to fix distinctly the epoch of the first employment of the laryngoscope in the investigation of laryngeal disease. In considering this question it was necessary to bear in mind the essential conditions under which laryngoscopy is practised. These were—1st. The visual ray from the observer's eye has to be directed to a part which, when the mouth is open, is hidden from direct view by the projecting angle formed by the base of the tongue and epiglottis. 2nd. The part to which the visual ray is directed—that is to say, the larynx—is not penetrated by light. To overcome these obstacles to laryngoscopy there are required, then (1), a small mirror placed at the back of the throat at such an angle that the visual ray can be directed into the larynx; and (2), an apparatus for concentrating the luminous rays, and projecting them upon the small mirror, so that they can be reflected into the larynx. For this latter purpose modern laryngoscopists generally use a second mirror (the ophthalmoscopic mirror of Rüete). The essential requisites of a laryngoscope were clearly perceived by Dr. Babington as early as the year 1829. At that period his inventive genius was directed to the subject, and he contrived a laryngoscope very similar to the one now in use. It consisted of a small laryngeal mirror, and a hand mirror for concentrating the light. The patient sat with his back to the sun, and while the illuminating mirror (a common back-hair glass) was held with the left hand, the laryngeal mirror was introduced with the right. Dr. Babington's labours did not end here. By a very simple mechanism, a tongue-depressor was united with the laryngeal mirror, and thereby one of the most serious obstacles to laryngoscopy was attempted to be overcome. This ingenious laryngoscope [instrument shown] was exhibited at the Hunterian Society on March 18, 1829; and a report of the meeting was published in the 'London Medical Gazette' of March 28, 1829. It was made by an optician named Elsworthy, and the invoice [shown] was dated June 23, 1829. In this laryngoscope a spring between the shanks of the laryngeal mirror and the spatula was fixed in such a way that by pressing the two handles together the tongue was depressed. Afterwards (between the years 1830 and 1835) Dr. Babington gave up the tongue-depressor, and had two instruments made very similar to those now in use, except that instead of being of glass they were of steel. The maker's name (Laundy) is stamped on one of the mirrors. In rendering justice to a distinguished physician, the author did not wish to detract from the credit fairly due to others who, at different times and independently of one another, had contrived an apparatus for inspecting the larynx. Dr. Czermak's great merit consisted in his having so simplified the instrument that it could be used by the many; and his talent and enthusiastic teaching had so prominently associated his name with the laryngoscope that his reputation would not suffer from a due recognition of Dr. Babington's claims. The author said it could not be denied that as early as 1827, Dr. Senn, of Geneva, tried to make use of a small mirror to examine the larynx of a child on whom he was about to perform tracheotomy. Dr. Senn was unsuccessful because he only employed one of the factors in laryngoscopy; and whilst he attributed his failure to "the small size of the mirror," it really depended on the non-illumination of the larynx. Dr. Senn's case, moreover, was not published in the 'Journal de Progrès' till the year 1829, a short time after Dr. Babington's description had appeared in the 'London Medical Gazette.'

Dr. GIBB said he was glad that the subject of the author's paper had been brought before such a tribunal as this Society, for the discovery of the laryngoscope would now be recorded in such a manner that the claims of the original inventor would not be overlooked. This was important not only to Dr. Babington himself, but also for the history of the instrument. He could not sufficiently express himself in terms of praise towards Dr. Babington for his own most ingenious invention, one that is already proving of immense value in the diagnosis and treatment of laryngeal affections. When Czermak visited London in 1860, the belief was then entertained from his writings and conversation, that Liston was the inventor of the laryngoscope, and that idea was entertained until quite lately. When he (Dr. Gibb) brought the subject before another society in 1862, he was informed by Mr. Streeter, of Harpur street, that Dr. Babington had to his knowledge used the instrument for many years, but he could not refer him to any published notice. Last year, however, this was rectified, and the original notice of the invention, as recorded in the 'Medical Gazette' for 1829, appeared in another journal, and indisputably settled the question as to Dr. Babington's claims in the matter; and in his (Dr. Gibb's) work recently published he had taken care to rectify what was, on his part, an unintentional act of injustice to Dr. Babington. He would observe, however, that Bozzini, of Frankfort, in 1807, conceived the idea of illuminating many of the cavities of the body; but so far as he (Dr. Gibb) could investigate the evidence, he had examined the nostrils only, and, therefore, was the first to practise rhinoscopy. Dr. Babington's great discovery occurred in 1829. He was followed by Selligue about 1833, an ingenious mechanic, mentioned by Trousseau and Belloc in their work on 'Consumption of the Larynx.' Beaumes, of Lyons, came next in 1838, and he practised rhinoscopy as well. Liston followed in 1840, Warden in 1844, and Avery in 1846. The last-named showed him (Dr. Gibb) his instruments in 1848, with some cases of cleft palate, although no observations were published. And, lastly, Garcia's researches were printed in 1855. There could be no doubt that most of these intuitively conceived the idea of inspecting the larynx; but as the priority of the invention now stands, Dr. Babington was the first discoverer of the laryngoscope, and the first to apply it either with the direct or reflected rays of the sun; Bozzini first practised rhinoscopy; and Garcia autolaryngoscopy. To revert, however, to the instruments of Dr. Babington, the simplicity of their construction and their utility were unequalled, and not surpassed by many of the instruments of more modern invention; the combination of laryngeal mirror and tongue-depressor in the same instrument was most ingenious. From what had been stated in the author's paper, and from a letter he had lately received from Dr. Babington himself, it was quite clear that the merit of using reflected light was wholly Dr. Babington's, who employed a small hand-glass to receive the rays of the sun, the patient's back being turned to the light. This merit has been claimed for others, but cannot be so for the future; and although the author has stated that Dr. Senn attempted to use a laryngeal mirror in 1827 upon a child, he (Dr. Gibb) did not see that it in any way affected the credit of Dr. Babington as the discoverer of the laryngoscope; and he once more tendered to him his grateful acknowledgments for what he had done for mankind by his simple, yet remarkable and highly-important invention.

Dr. COPLAND agreed with Dr. Gibb in the encomium he had passed on Dr. Babington. He felt sure that the Society would be glad to see Dr. Mackenzie's paper in its annals, and he (Dr. Copland) was proud of having introduced Dr. Mackenzie to the Society.

THE MEDICAL CIRCULAR.

WEDNESDAY, MAY 11, 1864.

THE MEDICAL COUNCIL.

The Medical Council has been sitting during the whole of the week, having concluded its labours only on Saturday; and if there has not been much actual business transacted, there has been at least an abundance of talking, all of which the Journals, both Medical and otherwise, have been at liberty to report, if they thought proper. Very few of them, however, have hitherto availed themselves of the privilege, and none of the non-medical journals have condescended to take any notice of the Medical Council at all. The reporter for one of our contemporaries is evidently not a Medical man, and therefore his reports, although exceedingly voluminous, and plentifully interspersed with "Cheers," and "Hear, hears," and "Oh, ohs," and "No, nos," all which are usual enough at public-house meetings and contested elections, are not very edifying to the Medical philosopher. We may just mention, *en passant*, that these noisy demonstrations on the part of the General Council are for the most part imaginary on the part of the reporters, or put in as a kind of spice or seasoning to the dreary monotony of the debates, for it is remarkable how gravely and attentively the members of the Council listen to each other's speeches; and, indeed, it is not likely that twenty-four gentlemen of acknowledged eminence in their Profession would indulge in shouts and cries which might be appropriate in a pot-house, but would be quite out of place in a learned and scientific and select assembly of the *élite* of the Medical Profession, meeting in the quiet Library of the Royal College of Physicians. A Medical man would hardly report that one of the speakers had attended the lectures of *Dr.* Abernethy, or represent Mr. Arnott as stating, without any qualification, that, *at an examination at University College in Surgery*, one of the men did not know the difference between the splint for the arm and that for the leg, and, when he came to apply it, he did not know whether it was for the front or the back of the arm. The transaction in question took place, it is true, in the walls of University College, but the examination was in no way connected with that institution, which was merely lent for the occasion to the examiners for the Army Medical Department—a circumstance which was distinctly pointed out by Mr. Arnott, but which apparently escaped the notice of the reporter. Again, it will puzzle some Medical readers to know why the reporters infer the great ignorance of some of the candidates for the Army Medical Department, because one of them, in defining the different kinds of aliments, wrote the following: "Of the albuminous sub-division (of food), perhaps the most common example is the hen's egg; of the fibrous, the meat of the ox or sheep; veal and pork, I believe, do not contain so much fibrin. Of the caseous, milk and cheese; of the gaseous, soda-water." Really, with the exception of the word *fibrous* being written instead of *fibrinous* in the second sentence, we cannot see much objection to this answer; and we only hope that the unfortunate candidate was not rejected on account of it. The real point of the mistake, as read by Dr. Parkes, was, that the candidate put all these substances under the head of *non-nitrogenous* bodies; but this point is entirely lost by an erroneous sub-division of the sentences on the part of the reporter. It is true that there were other very gross mistakes pointed out by Dr. Parkes, but the instance we have just quoted is, of course, mis-reported. The very striking case adduced by Dr. Sharpey, where a student tied the omo-hyoid muscle instead of the subclavian artery, is not at all alluded to, probably because the reporter did not see where the mistake lay: and so we find throughout that technical and medical and educational questions are often jumbled together in inextricable chaos, while sharp personal discussions are faithfully and accurately recorded.

A rather amusing instance of the latter is the discussion which was set up between Dr. Alexander Wood and Mr. Syme, on the subject of the preliminary examination required by the Scottish corporations from their Medical candidates. Dr. Alexander Wood affirmed that the education required by the Commissioners of the University of Edinburgh was lower than that required by the Dublin Apothecaries' Company, to which sally Mr. Syme replied that however low the standard of the University of Edinburgh might be, he could name one, the standard of which was lower still, namely, the *College of Physicians of Edinburgh*, of which Dr. Alexander Wood is the President, and also representative in the Medical Council. "When Greek meets Greek, then comes the tug of war," and when Scotchman meets Scotchman, pretty smart blows are evidently exchanged; and that both blows took effect in the present instance, may be inferred from the fact that there appeared a desire in several quarters that the observations should not be reported. The facts, however, *are* reported, and it is admitted that the requirements as to preliminary education made by the Universities of Scotland and the Royal College of Physicians of Edinburgh are lower than those demanded by the Apothecaries' Hall in Ireland.

With these and similar facts before our eyes, we are in some doubt still as to the expediency of publishing the reports of the debates in the Medical Council. It may be urged, it is true, that the exposure of the misdoings and shortcomings of the Medical corporate bodies may induce the inculpated parties to set their houses in order, and that the exhibition of the very ridiculous figure cut by some of the debaters may make them more cautious in future, and especially dissuade such as have glass windows from throwing stones at their neighbours' houses. But the very grave question remains, whether such revelations are particularly opportune at a period like the present, when the Government, the Legislature, and the public already look with no friendly feeling on the Profession, and when any supposed abuses may be seized upon to our further disadvantage. On the whole, we cannot but rejoice that the general press has not reported the late debates, and that the reports are not likely to be read by any but professional readers.

Passing from these observations to the more important inquiry as to the amount of work done, or of good accomplished, in the late sitting of the Medical Council, we must admit, with infinite regret, that the beneficial results are scarcely at all apparent. The avowed object of the Medical Act of 1858 was to introduce uniformity of education and qualification among the different Examining Boards, and to allow freedom and reciprocity of practice throughout the divisions of the United Kingdom. These were the ends for which Medical Reformers strove and struggled through a long series of years; and the only appreciable result at present is, that the higher distinctions have been pretty well swept away, and all ranks and orders of the Profession have been jumbled together into a heterogeneous and chaotic commixture, and, like the gold-diggers in a new gold country, each one must take care of himself, and fight his own way. The Medical corporations, instead of being ambitious to improve their curricula, are too often actuated by the Dutch auction system, and lower their standards to suit the lowest bidder; and the Medical Council has hitherto been powerless to shame the wrong-doers, or to correct the recalcitrant offenders against its own regulations. Every attempt to establish a minimum standard has failed, because it is practically found that "in the lowest depths there is a deeper still." The proposal to require a knowledge of Greek from aspirants to the Medical Profession was treated at the late meeting almost with derision, and even a knowledge of Latin was left optional. Almost the only corporate bodies which are able to take matters with a high hand, and to advocate and adopt a high standard, are the Universities of Oxford, Cambridge, and London; but the reason is not difficult to discover, for the two former are abundantly endowed from immemorial antiquity with pecuniary resources, and the last is a well-paid pensioner of the State.

SUMMARY OF THE WEEK.

THE SANITARY CONDITION OF CALCUTTA.

Reports have lately reached this country of the prevalence of severe epidemic disease in the capital of our Indian Empire, and it appears that the authorities are endeavouring to carry out measures of hygienic improvement. All our information tends to convince us that the sanitary state of Calcutta has long been most lamentably neglected, and that both the natural position of the city itself and the customs of the inhabitants are eminently unfavourable to the health both of the native and European population. Much of this insalubrity has been justly attributed to climate and geographical position, but still more is unquestionably due to the inefficient manner in which hygienic laws are enforced. The causes of the sickness and mortality in Calcutta have long ago been pointed out by Sir J. Ranald Martin, and we have been favoured with a copy of a pamphlet written by that eminent military surgeon and sanitarian, so long ago as 1847, entitled 'A Brief Topographical and Historical Notice of Calcutta: with a Sketch of the Rise and Progress of Sanitary Improvement in the East Indies.' In this little work Sir J. R. Martin gives a brief but luminous sketch of the position of Calcutta—in its relation to soil, sea, marsh, and jungle; and he relates his own struggles, made since the year 1821, to improve the sanitary condition of the city, by the removal of all *preventible* causes of disease. In these efforts he met with many obstacles, and very little encouragement even from the medical authorities of the city of Calcutta, till he relinquished his appointment as surgeon to the Native Hospital, partly driven from his post by a violent attack of fever, but also partly from the opposition he had encountered in carrying out his benevolent and prudent designs in promoting the pursuit of preventive medicine, as distinguished from the mere treatment of disease.

THE TREATMENT OF THE SICK POOR IN WORKHOUSES.

The newspapers have lately found room for the details of some inquiries instituted by the Poor-law Board, in reference to the treatment of poor persons in Bethnal Green, and much public indignation has been expressed on the subject. The local authorities of Bethnal Green have incurred a great amount of obloquy in consequence of the death of several persons from alleged neglect, and the matter is now undergoing a sifting and apparently impartial inquiry. The revelations made before the Poor-law Inspector are certainly heart-rending enough as to the treatment of sick paupers, but they disclose nothing new. Other parishes are quite as bad as Bethnal Green, and so-called guardians of the poor are elsewhere quite as heartless and quite as negligent as those of the eastern locality in question. But *they have not yet been found out*, and the Poor-law Board, although it has had plenty of enormities of a similar nature made known to it, thinks it best to keep things quiet, and support the authorities. In fact, had it not happened that Bethnal Green possessed in one of its Medical officers a man who was determined to tell the truth, regardless of consequences, the present inquiries would never have been instituted, and even now, by his threatened dismissal from office, he pays the penalty of his honesty. We boldly assert that the treatment of the sick poor in our workhouses is a disgrace to a civilized country, and that the Poor-law Board, however much it may think proper at spasmodic intervals to awake from its apathy, winks at the abuses, and concurs in the punishment of any Medical officer who desires to do his duty and to tell the truth. We desire to offer no opinion as to the treatment of able-bodied paupers, but as to the sick in workhouses, or in poor neighbourhoods, they have a right to merciful consideration, which at present they do not receive.

A Misappropriation of Public Funds.—The prosecution in the court-martial upon Surgeon-General Hammond has recently closed without establishing one of the charges set forth in the indictment against him. It is to be regretted that a quarter of a million of the public money should have been thus expended in a vain attempt to blast the reputation of an officer whose administration of one of the most important Government Bureaux has challenged the admiration of the Medical profession of this and foreign countries.—'American Medical Times.'

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

We have received the Minutes of the Council Meetings for the last week, but in consequence of the crowded state of our columns and the importance of some of the subjects discussed, we have thought it advisable to defer the publication of the results until the appearance of our next number, when we shall offer some observations on some of the more prominent topics.

DINNER OF THE GRADUATES OF THE UNIVERSITY OF ST. ANDREW'S.—PRESENTATION TO DR. DAY.

The first St. Andrews Graduates' University dinner was held at the London Tavern on Tuesday, the 3rd inst., and was a marked success. Dr. Richardson occupied the chair. Nearly one hundred graduates were present, and amongst the guests were the Right Hon. Lord Campbell, Dr. Brady, M.P., Alderman Sidney, M.P., Dr. Allen Thomson, the representative of St. Andrews University in the Medical Council, Mr. Robert Chambers, Mr. Mandy, Colonel Ogilvie, Mr. Glaisher, F.R.S., Mr. Erasmus Wilson, F.R.S., Dr. Gardiner Hill, Prof. Gamgee, Mr. J. R. Butlin, Mr. Jos. Knight, Mr. G. Clarkson Stanfield, Mr. Winwood Reade, &c. There were also present many eminent provincial graduates, amongst whom were Dr. Henry Day, of Stafford; Dr. R. U. West, of Alford; Dr. Ogden Fletcher and Dr. J. Shepherd Fletcher, of Manchester; Dr. Skinner, of Liverpool; and Dr. Davies, of Stafford. Communications expressive of regret at being unable to attend were announced as received from Mr. John Stuart Mill, Right Hon W. Cowper, M.P., Captain Salt, M.P., W. Ewart, Esq., M.P., Dr. Noble, Sir Ranald Martin, and the Director-General, Dr. Gibson.

The Chairman, on proposing the toast of the evening, "Success to the University of St. Andrews," was received with great enthusiasm. When the applause had subsided, he said:—He knew it was only necessary to name the toast to secure its hearty acceptance; and well might graduates of St. Andrews remember with honour their venerable University. As our nobles of England look with pride on their estates, on the noble old trees and stately palaces, as their hearts throb with the satisfaction that these are their patrimonies: so, too, the graduate of St. Andrews can look back on his University, and say there is his patrimony, one of the most ancient of all, and crowded with triumphs of the past. The chairman next described in rapid review the lives of many eminent men who had adorned the university—viz., Cardinal Beatson, the admirable Crichton, Arthur Melville, John Knox, Thomas Chalmers, Lord Chancellor Campbell, David Lindsay, J. Napier, inventor of the system of logarithms, Adam Fergusson, Lord Elgin, who brought over the Elgin marbles, Lord Erskine, and, amongst Medical men, Arbuthnott, and the immortal Jenner, the discoverer of vaccination, to whose memory an earnest tribute was paid. He (the chairman) had spoken briefly of the patrimony, he had also given the ancestry of the University; and he asked:—If the greatness of men depended upon their influence over the destinies of the world for good, what University in any part of the world had given birth to so great a family? In all departments of human knowledge, in science, arts, politics, religion, law, literature, those men whose names he had read were the men who had stood first and foremost, not as the followers, but as leaders of learning and civilization—

> "Their souls were like the stars, and dwelt apart;
> Their voices had a sound, 'twas like the sea."

(Loud cheers.) Again, the chairman said, that the success of the University was dear to Medical men specially, for the liberal manner in which she had advanced medicine. In opening her doors to all Medical men who were prepared to meet a fair and practical examination, the University of St. Andrews had conferred national not less than professional advantages. For was it not for the benefit of the public that men of middle life, engaged in the active duties of practice, should have an inducement put before them to learn up all the new thought of the day; to learn what progress had been made since they were pupils; to add, if he might so place it, experimental knowledge to their own ripe experience, and to be at one and the same time the masters and students of their art? And did it not truly raise the educated and respected practitioner who had won his way in his locality; did it not raise him in social status to gain, after fair competition, an academic degree that placed him in legal rank with the Serjeant-at-law and the Dean of the Church? He (the chairman) thought so. He regretted that this liberty afforded so long by the University had been almost taken away; and he held that, as a matter of principle, it was the duty of the graduates of St. Andrews never to rest until that liberty was reclaimed in all its fullness. (Cheers.) In conclusion, the chairman drew attention, in the following terms, to the duties of graduates to their University in the present. Time was when no University existed; but perchance where it now stands there was a rolling sea, a wild wilderness, a gorgeous forest, or a barren-rock; and time may come when again the old University shall sleep under the waters, and when we, too, and all the memories of it and of us, like the baseless fabric of a vision, shall be lost and forgotten. Into that eternity of the future it is no duty of ours to look; but we have duties of the present which, under the governances and all-wisdom of Nature, are more important than the deepest insights into what shall be. Such duties relate to present work and action; they tell us that, while loving as brethren, it is our great task, as representatives of an University crowned with many glories, to see that these glories fade not in our possession, but that there shall pass into the hands of our children this roll of illustrious names, with others added to it by ourselves, not less honoured and not less useful. Success to the University of St. Andrews.

The toast was drunk with all the honours, and with protracted cheering.

After the toast, the presentation of a testimonial was made to Dr. Day, of St. Mary Church, Torquay, the late eminent Chandos Professor in the University. The testimonial, which was extremely handsome, bore a suitable inscription, intimating that it was presented to him by 158 graduates, in token of their admiration of his labours in literature, science, and Medicine, and in special recognition of the services he had rendered to the University during his fourteen years of office. The chairman expressed his deep regret that Dr. Day, owing to the impaired condition of his health, was unable to attend, and he hoped that the offering now made to him would be a constant source of happiness and usefulness. Dr. Day would find in the richly-carved cabinet the work of the greatest of English artists in wood-carving, Mr. Rogers, the illustrated edition of the "Règne Animal" of the illustrious Cuvier—a work which would bring the whole of the animal kingdom within his reach, and would grow more and more valuable as life advanced. He concluded by proposing health and long life to Dr. Day—a sentiment that was most heartily received. Dr. Day, of Stafford, in a speech, marked by much good feeling, taste, and eloquence, received the testimonial on behalf of his relative and namesake.

In addition to the above-named toasts, the usual loyal toasts were proposed, as well as "The Army, Navy, and Volunteers," responded to by Colonel Ogilvie; "The Houses of Lords and Commons," responded to respectively by Lord Campbell and Dr. Brady, M.P.; the "Chairman," by Dr. Day; "The Medical Council of Education" by Dr. Dobell, responded to in an eloquent and, at the same time, common sense speech by Dr. Allen Thomson; "Success to Literature," responded to by Mr. Robert Chambers; "The Fine Arts," proposed by Mr. Chambers, and responded to by Mr. G. Clarkson Stanfield; "Science and the Learned Societies," proposed by Dr. Semple, and responded to by Mr. Glaisher; "The Bar," proposed by Dr. Edmunds, and responded to by Mr. Knight; "The Vice-Chairman and

Committee," proposed by Mr. Erasmus Wilson, and responded to by Dr. Paul; and "The Ladies," proposed by Dr. Sedgewick, and responded to by Mr. Winwood Reade. Taking it altogether, the first dinner of the University of St. Andrew's will not soon be forgotten. The music was under the direction of Mr. Land, and all the arrangements were in excellent taste. Amongst other points of "ancient novelty" was the introduction, by the Chairman, of the old and now almost forgotten classical grace before meat, "*Sit nomen Domini benedictam. Amen.*" And after meat the three words, *Deo gratias. Amen.* These graces, so short and yet so expressive, told with excellent effect. We can only hope that the St. Andrew's graduates' dinner of the 3rd of May, 1864, may be the forerunner of many others equally successful and happy: beyond the mere enjoyment of the hour, they revive dormant friendships, and supply the mind with remembrances that cheers it on, in the hope that it may again be satisfied.

DR. DAY.

The large gathering at the dinner of the St. Andrew's Graduates evinced the deep respect in which Dr. G. E. Day is held by his professional brethren. It cannot be less pleasing to him than it is creditable to the Profession, that they should recognise useful services and high intellectual attainments in a manner so earnest and spontaneous. Few men have done more than Dr. Day towards raising the status of the order of general practitioners by his consistent efforts to associate them with his University.

Dr. Day has long held a high place in Medical literature. It is chiefly through his indefatigable labours that the works of some of the ablest German physiologists have become standard treatises in this country. He has familiarised us with their latest researches, and has echoed their half-uttered whispers to provoke the ingenuity and stimulate the inquiries of English investigators. His editions of Simon's 'Animal Chemistry,' Rokitansky's 'Pathological Anatomy,' Vogel's work on the same subject, and Lehmann's 'Physiological Chemistry,' are honourable monuments of his industry and talent, and prove how great is the obligation which the Profession owes to him for labours always arduous and not usually so popular as they are valuable.

Dr. Day commenced his professional career in London, where he held the appointments of Physician to the Western General Dispensary, and Lecturer on Materia Medica at the Middlesex Hospital. About the same time, we believe, he was a contributor to the 'Medical Times,' and was London editor of the 'Edinburgh Journal.' He quickly made for himself a high reputation among men of science; we need not be surprised, therefore, that when a vacancy occurred in the Chair of Chandos Professor of Medicine at St. Andrew's University, he was selected, although yet a young man, to fill that important post. From the moment of his election he devoted himself to the task of raising the character of the University, and making it the Alma Mater of the more ambitious among English students and practitioners. His extensive literary connection in England gave him facilities that few other men possessed, and his exertions soon bore fruit. The publication of the Examination papers in all the journals maintained an interest in the University; while the questions showed that the scientific attainments that were demanded made the degree honourable to its possessor. Practitioners from England flocked to the quaint old city, and were charmed not less by the courteous and friendly bearing of its distinguished Professor of Medicine and Anatomy, than by the beautiful coast scenery that skirted its magnificent bay, and its interesting relics of the olden time, when Scottish worthies were making the romance which more recently has given its chief grace to Scottish literature.

Dr. Day is personally known to so many of our readers, that it is only necessary for us to express the hope that he may speedily find his health restored under the influence of the genial climate of South Devon, to elicit a wide and cordial response. The one thing wanted at the recent banquet was the presence of the learned Doctor himself, to receive in person the splendid testimonial which the esteem and kindness of his numerous admirers had provided. It will be, however, gratifying to him, in his forced retirement, to know that nearly a hundred graduates of St. Andrew's assembled in London to do him honour, in grateful recognition of his valuable services to Medical science and literature, and of his courteous and honourable character as a professional brother.

REPORTS OF SOCIETIES.

(Continued from page 317.)

Dr. BABINGTON said that perhaps he ought to have been silent, but he wished to say a few words. At the time the instruments were invented, a great deal was being said about infiltration of the glottis, and it occurred to him that it was desirable to seek means of examining the glottis more narrowly. With this instrument he had seen ulceration on the epiglottis, but he confessed that he did not contemplate looking through the glottis. He felt exceedingly obliged to Dr. Mackenzie and to Dr. Gibb, although he considered that he had been praised far too highly.

Mr. THOMAS BRYANT read a paper on

TWO CASES OF STONE IN THE BLADDER OF THE FEMALE TREATED BY RAPID URETHRAL DILATATION, WITH REMARKS ON THE OPERATION.

The author commenced by giving the history of two cases, of which the following are brief notes:—*Case* 1.—H.C., aged 52, admitted October 13, 1862. She had had symptoms of urinary irritation for eight months, and for three had been quite unable to retain her urine. On November 19 the stone was removed by rapid urethral dilatation, and it measured 1¼ inch by 1 inch in diameter. The operation was followed by immediate relief. On the day following the patient could hold her urine for twenty minutes, and in a week for many hours, and in three weeks she left well. *Case* 2.—Ann C., aged 35, was admitted on February 17, 1864. Urinary symptoms had existed for seven months and were very severe; the urine was full of pus, mucus, and was intensely fetid. The least examination caused her great pain. After rest in bed for several weeks these symptoms had improved, and on March 5 the operation was performed. Chloroform was given, and the urethra rapidly dilated by Weiss's dilator. The stone was then removed, but little difficulty being experienced in its removal. The calculus measured 2 inches by 1½ inch in diameter, and 5¼ inches in circumference, weighing 2 oz. 2 dr. The next day the patient could hold her urine for fifteen minutes, on the second for forty, on the third for two hours and a half, and on the fifth day for five hours. A small slough separated on the sixth day from the urethra, and during an examination the finger was introduced again into the bladder, which caused some little inconvenience; but this gradually disappeared, and on April 5 she was able to retain her urine for five hours. She is now convalescent, having good power over her bladder for three or four hours. The author then passed on to the consideration of the dilatability of the female urethra, and quoted many interesting cases, which were tabulated, in which a calculus had been expelled by natural efforts, and in which *no* incontinence of urine was the result. He then proceeded to consider the operation of urethral dilatation as a means of removing a calculus or foreign body; and gave an analysis of twenty-eight cases, which he had tabulated, in which he proved that incontinence of urine resulted in only four out of the twenty-eight examples and that in these four the dilatation had been *slowly* performed. He then considered in detail many of the cases, and enlarged upon the best mode of performing the operation. The subject of urethral lithotomy next obtained

notice; and it was proved that an incontinence of urine was a common result of the operation—nine subjects out of twenty being left in such a condition. Removal of a calculus by lithotrity was then touched on, and the subject of vaginal lithotomy introduced, the author indicating the exceptional cases in which either operation may be required. The following conclusions were then drawn up:—1. That the female urethra may be dilated to a considerable extent with facility, and without danger. 2. That *slow* and tedious dilatation of the urethra, by sponge tents or other means, appears to be injurious. 3. That *rapid* urethral dilatation, with the patient under the influence of chloroform, is the safest and most expeditious method of removing all average-sized calculi and foreign bodies from the female bladder; for calculi one inch in diameter in children, and even two inches in adults, have been safely extracted by this practice. 4. That the operation of incising the neck of the bladder and urethra is one of danger, and should be laid aside. 5. That lithotrity is a valuable operation in cases in which a stone cannot be safely removed by rapid urethral dilatation—that is, when the stone is very large, and when the bladder is healthy; and that it is the best practice to remove the broken fragments by the forceps as speedily as possible. 6. That vaginal lithotomy is an operation of value when the other modes of operation are inapplicable; but that, as a general practice, it is not required.

Mr. URE said the Society must feel indebted to Mr. Bryant for his valuable paper. He (Mr. Ure) believed that there were cases in which lithotrity was advisable. He then related a case in which the sub-pubic operation of lithotomy had been performed with good results, no incontinence remaining.

Mr. WALTER COULSON congratulated Mr. Bryant on his paper. For his own part, he (Mr. Coulson) much preferred the operation advocated for the removal of the stone from the female bladder to vaginal lithotomy for two reasons—first, because there was risk of a vesico-vaginal fistula following as a consequence of the latter operation; and secondly, because the operation itself was much more tedious, and involved a long confinement to bed. Still, in the hands of Mr. Baker Brown and Mr. James Lane, the results had been very satisfactory. He doubted, however, whether other surgeons, who had not the same experience in the operation for vesico-vaginal fistula, would be equally successful. Mr. Coulson alluded to a case in which he had removed a phosphate calculus the size of a large walnut. He had used Weiss's instrument, and was surprised to find how readily the urethra could be dilated. The patient did very well, was able to sit up three days after the operation, and could hold her water for two hours. No incontinence followed. He mentioned another case, at which he had assisted, when a much larger stone had been removed by urethral dilatation, and where no incontinence resulted a fortnight after the operation. Referring to what had fallen from the last speaker, he did not think it was ever necessary to incise the urethra, as the tissues were capable of very considerable dilatation. There was one passage in Mr. Bryant's paper in which he could not concur. He stated that vaginal lithotomy might be advisable where the calculus was large. Should the size of the calculus be such as to render its removal entire through the urethra after dilatation impossible, he should be disposed, first, to dilate the urethra, and then to crush the calculus, not with the lithotrite, but with a forceps, as used in lithotomy, in the male when the stone is too large to come away. He considered this proceeding preferable to vaginal lithotomy, for should the stone be so large as to render impossible its removal through the urethra, it would be necessary to make an incision that would involve pretty nearly the whole length of the original wall of the bladder. This was a serious objection. Therefore, where the calculus was very large, Mr. Coulson preferred rapid urethral dilatation, and crushing, when necessary, to either vaginal lithotomy or to urethral dilatation, with incision of the urethra.

Dr. WYNN WILLIAMS said that a specimen had been shown him by Mr. Clements, of Shrewsbury, of a crochet needle removed by the Messrs. Weiss's dilator from the female bladder. It was sacrusted by a deposit as large as a pigeon's egg, and had been in two years. The patient did well, and had no incontinence.

Mr. SPENCER WELLS said that there could be no doubt of the difficulty of dealing by lithotrity with such a case as that described by Mr. Henry Thompson. A large stone and small irritable bladder clearly indicated that if dilatation were inadmissible, some form of lithotomy—vaginal, urethro-vaginal, or the lateral operation so successfully practised by Dr. Buchanan, of Glasgow—was called for. But in a case where the stone was of moderate size—say, from half an ounce to an ounce—and the bladder of moderate capacity—say, from four to six ounces—it was a serious question whether lithotrity or dilatation should be preferred. Mr. Bryant's proofs against slow dilatation were conclusive; but those in favour of rapid dilatation did not appear sufficient to induce us to reject lithotrity in cases to which it is applicable. Lithotrity is a very easy operation in women. It may be performed without uncovering them, and by injections through a large catheter the whole of the fragments may be removed at one sitting. There is no fear of any incontinence of urine. But dilatation is very uncertain. In a very important case which had come under his (Mr. Wells') care some years ago, he had asked several of the most experienced London and provincial surgeons what their experience of dilatation was, and all had agreed that it was extremely uncertain, and that incontinence might follow a very moderate degree of dilatation. He treated this case most successfully by lithotrity. One surgeon said that he had dilated in nine cases, and seven were "dribblers" for the rest of their lives. Mr. Bryant's facts were strongly in favour of rapid dilatation; but were not strong enough to prove its superiority to lithotrity in cases where lithotrity was applicable.

Mr. HENRY THOMPSON regarded the paper as a valuable contribution to practical surgery, because it was impossible for any one surgeon to come to logical conclusions respecting the best mode of treating these cases from his own experience alone, stone in the female being, comparatively speaking, a rare affection. Mr. Bryant had contrasted the method of rapidly dilating the urethra by means of Weiss's instrument with that of slowly dilating it by sponge tents. It might be regarded, perhaps, as generally agreed that the latter method was not a desirable one. This left for consideration the treatment by lithotrity, by incisions, and by rapid dilatation, as well as that in which the two latter were combined. With regard to lithotrity, although he approved of it for stones of moderate size, he was quite sure that all who had attempted to remove a large stone at one sitting by this means encountered difficulties and risks of no ordinary kind. The bladder soon became empty, and the manipulation and removal of large, sharp, and angular fragments in that condition he considered a very hazardous proceeding, and one which probably involved more damage to the urethra, to say nothing of the bladder, than the removal of a good-sized stone entire. He was not quite sure whether the combination of incision with some dilatation had received all the attention it merited. For large stones he could speak in high terms of its value. This might be illustrated by briefly referring to a case which had occurred in his own practice two months ago. He had been called by Dr. Ashurst, in Kent, to see a lady, aged seventy-seven years, who had suffered very severely from the presence of a large calculus. She was placed under chloroform. Mr. Thompson then dilated the urethra so as to admit the left finger easily; and having thus examined the stone and found that it was too large to pass by any dilatation he thought proper to employ, he made an incision downwards in the median line, using the index finger as a director, and divided mainly the floor of the urethra and soft parts beneath, after the manner recommended by Mr. Fergusson, incising only very slightly the neck of the bladder. Having done this he extracted, slowly and carefully, a stone 2¼ inches long by 1¾ inches wide, and weighing nearly 2½ ounces. He then introduced Marion Sims' vaginal speculum, and closed the incision by metallic suture,

as when operating for vesico-vaginal fistula. The result was perfect. The patient, notwithstanding her age, was now perfectly well, walking about, and retaining her urine for three hours with ease. For very large calculi he should prefer again to adopt this method of trusting solely to the large amount of unaided dilatation which would be required.

The AUTHOR, in his reply, expressed his pleasure at having elicited the details of several interesting cases from Mr. Ure, Mr. Thompson, and Mr. Birkett. The success of Mr. Ure's case was very good, but it was open to a doubt whether the calculus might not have been removed more readily and with equal safety by rapid urethral dilatation than by the operation which had been performed. He would remind Mr. Wells that he (the author) had not disputed the possibility of removing a calculus from the female bladder by lithotrity; for in certain cases this operation was of great value; but his aim had been to show that the same end might be secured in the majority of cases by a simpler and more expeditious practice. The expression of the surgeon which Mr. Wells had quoted was very singular; it would be of great interest to have the details of the several cases to which he had alluded. Mr. Thompson's case was one of great practical interest; the operation he had performed for the removal of the stone was probably the best. He (the author) thanked the Society for the kind way in which they had received his communication.

Mr. BIRKETT showed some

CALCULI REMOVED FROM A WOMAN WHO HAD PROLAPSUS UTERI.

She was a patient of Mr. Roper, of Shoreditch. She had had prolapsus of the uteri and bladder for seven years. Three months ago she expelled fourteen stones. When Mr. Birkett saw her it was easy to take hold of the bladder and rattle the stones in it. A good many were extracted by dressing forceps. Dr. Odling had analysed them, and found them to consist of seventy-five parts of phosphate of lime, twenty parts of carbonate of lime, a trace of triple phosphates, alkaline salts, and organic matter. Mr. Birkett said that having shown them to a Medical man from Boulogne, he was asked if the patient had not had prolapsus of the uterus and bladder. Mr. Birkett wished to know if any of the members present had observed such calculi in prolapsus of the uterus and bladder.

Dr. BASHAM said the calculi were very curious in a chemical point of view. They were composed in the same proportions of phosphate and carbonate of lime as bone.

Dr. BABINGTON thought that phosphatic calculi were rather prostatic than vesical, and were generally found with deteriorated health.

DEATHS.

BAGSHAWE.—On the 2nd inst., at Connaught square, Frances Elizabeth, the wife of F. Bagshawe, M.B., aged 28.

COOKE.—On the 1st inst., at Cambray, Cheltenham, C. T. Cooke, M.R.C.S.E., aged 69.

COOPER.—On the 2nd inst., at Ixworth, Suffolk, Henry Ralph Cooper, M.R.C.S., aged 49.

CURTIS.—On the 27th ult., at Alton, J. W. Curtis, M.D., aged 50.

DAWSON.—On the 26th ult., at Southgate, Wakefield, W. Dawson, M.R.C.S.E., Alderman of the Borough, aged 65.

KELLY.—On the 30th ult., at Notting hill, John Kelly, M.D.

ORTON.—On the 25th ult., at Beeston, Notts, Richard Orton, M.R.C.S.E., aged 24.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 28th ult.:—Arthur Bayley Adams, Lymington, Hants; William Akerman, St. Just; Frederic Charles Bailey, L.S.A., Woolwich; Joseph Birt, Leamington; John Dawson, Great Yarmouth; William Soltan Eccles, Plymouth; Walter Hardin, Woolwich; Edmund Woods Hawkins, Commercial road; Ernest Arthur Hudson, Queen Ann street; William Frederick Knapp, Headington; Thomas Henry Knott, Bath; George Welland Mackenzie, Tiverton, Devon; Henry Maturin, Lymington, Hants; Edward Norton, Birmingham; George Huntsman Shaw, Attercliffe, near Sheffield; Thomas Francis Raven, Cambridge; Henry Rayner, Hythe, Kent; Frederick William Richards, Winchester; James Taylor Smith, Newcastle; Henry Octavus Steele, Harlsey, Yorkshire; Charles Meymott Tidy, Cambridge heath; Charles Humphrey Weld, Tenterden, Kent.

The following were admitted Members on the 29th ult.:—Charles Bradley, Nottingham; Ralph Burnham, Preston, Yorkshire; Frederick Chabot, Camberwell road; William Robert Coward, South Shields; Frederick John Cropp, Clapham; Herbert Davis Llanybyther, Carmarthenshire; Samuel Duckering, L.S.A., Grantham; Edward Dyer, Canonbury; Vincent Frederick Eck, Cleveland square; William Nicholas Heygate, Hanslope, Bucks; Henry Hope, Richmond; Daniel Iles, L.S.A., Fairford, Gloucestershire; George Frederick Sankey, Maidstone; Joseph Needham Scrope Shrapnel, L.S.A., Isle of Wight; Francis Snaith, Boston, Lincolnshire; Robert Wrentmore Thomas, Bristol; William Warwick Wagstaffe, Lambeth; James Whitworth, Port Talhal, Glamorganshire; David Martin Williams, Calcutta; Algernon William Winn, Scarborough; Robert Winter, Hampstead.

ANATOMY AND PHYSIOLOGY.—The following gentlemen passed their primary examinations at a meeting of the Court of Examiners of the above College on the 21st ult., and when eligible will be admitted to the pass examination:—C. T. Aveling, St. Thomas's; Marcus Beck, University College; Edward Bourfield, Birmingham; R. D. Broughton, St. Bartholomew's; Richard Bugden, Westminster; Laurence Corban, Cork; H. P. Gordon, Dublin; Alfred Harwood, Guy's; E. M. Little, King's College; John Loane, London Hospital; E. M'C. M'Cready, Dublin; * H. T. Nettleton, Westminster; H. D. Reynolds, Guy's; Arthur Richardson, Charing-cross; J. A. Richardson, Hull; F. M. Rickard, Guy's; H. T. Ryder, Middlesex; W. L. Shepherd, St. Bartholomew's; Thornton Gerald Simpson, Guy's; Joseph Thompson, University College; E. A. Trimnell, Guy's; Osmond Vincent, King's College; J. H. Wathen, University College; G. W. Wigin, Leeds; T. H. Willan, St. Bartholomew's; O. T. Williams, Dublin.

* This gentleman was admitted a Member on the 26th ult.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 28th ult.:—Thomas Edward Blick, Islip, near Oxford; William Henry Sutcliffe, Manchester.

The following gentleman also on the same day passed his first examination:—David Howell Thomas, St. Bartholomew's Hospital.

PRELIMINARY EXAMINATION IN ARTS.—The following gentlemen passed this examination, and received certificates of proficiency in General Education, on the the 29th and 30th ult.:—Dacre Fox and James Tudor Phillips, Certificates of special proficiency; A. J. Baker, Whitehead's grove, S.W.; Thomas Budd, Brockham, Surrey; Alfred Cuff, Camden road villas; H. W. Folwell, Gloucester street; Dacre Fox, Stowmarket, Suffolk; Thomas W. Gower, Rochford, Essex; John George Hurford, Nelson square; Albert Iles, Fairford, Gloucester; William A. Kibler, Hackney; Edward Rodolph Luard, Rathbone place; Albert M'Cann, Parliament street; Richard Alfred Morrish, Ledbury; H. R. Moulin, Guernsey; Robert A. Painter, Shoreditch; Michael Perry, St. Bartholomew's Hospital; James Tudor Phillips, Newcastle Emlyn; Robert Sheffield, Swallow's gardens; Charles B. Sweeting, Nassau, Bahamas; Thomas Charles Thornicraft, Faversham; Frank Sextus Tuck, Seaford; Richard L. Wilson, Uppingham; Thomas Wilson, Manchester; John Skelbeck Wood, Wakefield; Edward Young, Hawkhurst.

ROYAL INSTITUTION OF GREAT BRITAIN.—Annual Meeting May 2, 1864, William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair. The Annual Report of the

Committee of Visitors for the year 1863 was read and adopted. The amount of contributions from members and subscribers in 1863 amounted to 3,423*l.*; the receipts for subscriptions to lectures were 716*l.* 12s. 6d.; the total income for the year amounted to 5,532*l.* 10s. 7d. On Dec. 31, 1863, the funded property was 30,107*l.* 14s. 11d.; and the balance at the bankers', 1,056*l.* 14s. 9d., with six Exchequer Bills of 100*l.* each. Fifty-five new members were elected in 1863. A list of books presented, amounting in number to 121 volumes, accompanies the Report, making, with those purchased by the Managers and Patrons, a total of 561 volumes (including periodicals) added to the library in the year. Sixty-three lectures and nineteen evening discourses were delivered during the year 1863. Thanks were voted to the president, treasurer, and secretary, to the committees of managers and visitors, and to Professor Faraday and the other Professors, for their services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President—The Duke of Northumberland, K.G., F.R.S. Treasurer—William Pole, Esq. M.A., F.R.S. Secretary—Henry Bence Jones, M.A., M.D., F.R.S. Managers—George Busk, Esq., F.R.C.S, F.R.S.; Warren De la Rue, Esq., Ph.D., F.R.S., Sir George Everest, C.B., F.R.S.; John Peter Gassiot, Esq., F.R.S.; John Hall Gladstone, Ph.D., F.R.S.; William Robert Grove, Esq., M.A., Q.C., F.R.S.; Sir Henry Holland, Bart., M.D., D.C.L., F.R.S.; John Lubbock, Esq., F.R.S.; John Carrick Moore, Esq., M.A., F.R.S.; William Frederick Pollock, Esq., M.A.; Robert P. Roupell, Esq., M.A., Q.C.; Major-Gen. Edwin Sabine, R.A., D.C.L., Pres. R.S.; The Right Hon. Lord Stanley, M.P, F.R.S.; Joseph William Thrupp, Esq.; Colonel Philip James Yorke, F.R.S. Visitors—John Derby Allcroft, Esq.; The Hon. and Rev. Samuel Best; John Charles Burgoyne, Esq.; George Frederick Chambers, Esq.; John George Dodson, Esq., M.P.; Christopher Darby Griffith, Esq., M.P.; Henry Harwood Harwood, Esq.; Thomas Henry, Esq.; Thomas Hyde Hills, Esq.; Harry Mackenzie, Esq.; John North, Esq.; The Lord Overstone, M.A., F.G.S.; Edmund Packe, Esq.; The Earl Stanhope, D.C.L., F.R.S., Pres. Soc. Antiq.; George Tomline, Esq., M.P.

THE BERLIN SCHOOL OF PATHOLOGISTS AND THEORIES OF PATHOLOGY.—The Pathological Institute where the observations in Pathological anatomy are incessantly carried on, headed by Virchow, is a part of the great "Charity Hospital" to which are conveyed for dissection and examination all the bodies of the dead who expire therein. This hospital contains some thousands of patients, and the quantity of exanimate material it furnishes to the pathologist is immense, of every variety, from the youngest fœtus in utero to the very oldest of both sexes. In this particular it can hardly be exceeded by any similar seat of study in the world; but does not perhaps exceed that of Vienna. It has a department of physiological chemistry. The branches that are taught in it are physiology, histology, and pathological anatomy. In any correct scheme of study, these, of course, run very much together, and ought to be inseparable. The Institute exists for the one purpose, which the study of all these equally promotes—viz. to ascertain the *true* character of animal tissues, normal or morbid, and the exact nature of the functions of those tissues. The means of research for the first is, of course, the microscope. Most, if not all, of the students are graduated physicians; but those in the department of microscopic anatomy (so far as there is any distinction in the departments) are men intent on the solution of scientific problems, inquirers in an advanced and advancing scientific stage. Some of them are men actively ambitious of ascertaining new facts which shall invalidate received ones, or enable them to explain the latter as errors. It is the distinction of the views accredited here that they are the fruits of the labour and research not of isolated observers, nor of occasional though successful research, but of a number of observers constantly in pursuit of one purpose—that already mentioned. Whatever is known to one is to the others; and most frequently one point, if it have any novelty, is the subject of various and general, though perhaps not formally *combined*, research. I do not imagine a better place of investigation in these respects.—Dr. R. K. Browne, 'American Medical Times.'

BRITISH PHARMACOPŒIA.—In concluding a lecture on the "British Pharmacopœia," at the Pharmaceutical Society, Dr. Attfield remarked that although the fusion of the three Pharmacopœias into one must be considered to have been accomplished in a most satisfactory manner, and be a source of congratulation to all, yet it is open to serious question whether the compilers of the work have accurately represented the advancement made in pharmacy during the past thirteen years. The comments made and published show that while the Materia Medica part of the book may be regarded as a success, the preparations and compounds are, to a great extent, a failure. Such a result may be fairly ascribed to want of pharmaceutical co-operation in the work of compilation. Had the book been thrown open to comment before publication instead of after, or the opinions of pharmaceutists elicited in some other way, a Pharmacopœia might have been produced which would have commanded the confidence of all interested in its pages.

THE FIRST FEMALE MEDICAL PRACTITIONER IN ENGLAND.—After a desperate struggle against numerous obstacles, Miss Garratt has at last found her way to a medical examining board, has passed her first examination, and become what our cotemporary the 'Lancet' was pleased to designate the "Pet of the apothecaries." Without pretending to know too much of the secrets of an examining board, we may state that Miss Garratt's examination reflects upon her the highest possible credit, and that both in the written and oral parts of it she displayed an accuracy of knowledge, a precision and a breadth, which surprised the examiners, and which are rarely seen in the court. In chemistry she wrote an essay on the meaning of the terms "specific gravity," entering most carefully and minutely into the *rationale* of the process, and supplying even the mathematical formulæ for calculation. She wrote a second essay on isomorphism and isomerism, adducing copious illustrations of isomorphic and isomeric bodies, and giving the modern views on those points. In anatomy, she described, we believe, without a single error, one of the most difficult portions of the brain; and in physiology she rendered with equal skill and perfection an account of respiration. This was the written ordeal. In the oral—botany, materia medica, the uses and composition of drugs, anatomy, physiology, and chemistry, were subjects of trial; in all of which she evinced an equally sound advancement, and we know that the examiners were specially struck with the fact, that while Miss Garratt's learning was so well shown, the manner in which it was displayed was collected, natural, and tinged with no approach of affectation. When we consider the immense difficulties under which this young lady has acquired her knowledge; when we state what we are assured is the fact, that her lessons in anatomy have been taken almost at midnight, when all the male students had long departed; and when we are informed that at this moment she is actually acquiring her hospital practice in the humble capacity of a nurse at the "London," we cannot admire too heartily the perseverance, courage, and self-sacrifice that have been manifested. Miss Garratt, in our opinion, deserves, and has fully earned, admission to the same honours as any other praiseworthy student of medical science and art, and we think it the narrowest policy for any college or board to refuse her examination. We make the above observations, still holding an opinion which we have before expressed, that it is quite an open question whether women generally can follow medical practice as a means of livelihood; but we contend that they ought to be allowed to try. Then if their efforts fall through of themselves there is no one to blame. But flatly to deny them the opportunity of making the attempt is simply to excite a public sympathy which scarcely can be said to be misdirected, and which is far more injurious to the medical profession at large than the introduction into their ranks of any number of female practitioners.—'Social Science Review.'

THE TRICHINA DISEASE.—A physician of Davenport, Iowa, writes,—That a lady had long been afflicted with the symptoms now traced to infestation by trichinæ. She was a native of Holstein; emigrated to the United States. She recovered, except a disability to use her hands in piano-playing. She returned to Altoona (Holstein), and was there operated on for malignant tumour of the breast. When the muscles were bared by the scalpel, trichinæ cysts were found in them. She died of the malignant disease, but on autopsy her muscles were found filled with encysted trichinæ *still alive*. It must have been ten years since she had consumed the trichinæ-infested flesh.

CASE OF POISONING BY PHOSPHORUS.—The following is the chemical evidence in a case of poisoning by phosphorus. The viscera were taken to Dr. Herapath twenty days after the death of the infant, which had been buried for nearly that time. The history of the case and symptoms led to the suspicion of poisoning by phosphorus. Dr. W. B. Herapath detailed the chemical examination of the viscera, &c., which was as follows:—"First, they were seriatim removed with great care on clean porcelain vessels to the interior of a photographic camera, and examined in the dark for evidence of luminosity. None presented itself, however, and the contents of the viscera were equally devoid of any such appearances. 2nd. The contents of the stomach were treated with pure ether. The etherial fluid decantered and filtered reduced the salts of gold and silver in such manner as a very minute trace of free or inflammable phosphorus would produce. The residual acid fluid was next tested by Mitscherlich's plan, by distillation with sulphuric acid, but without any corroborative evidence of the presence of phosphorus. 3rd. The same acid fluid was now tested by Scherer's distillation with zinc, and the evolved gas, chiefly hydrogen, passed through ammoniacal nitrate of silver; a black precipitate resulted, too minute in quantity to further test for phosphorus. This gave doubtful evidence of phosphorus existing as phosphorous acid in the contents of the stomach. 4th. The examination of the stomach's contents gave indications of phosphorous in the free state by the ether test, and probable evidence of phosphorous acid by Scherer's mode of testing for phosphuretted hydrogen. 5th. The whole intestines having been slit up for examination, the contents of the large intestine were carefully collected, amounting to two drachms of yellow pasty fæcal matter. This was first tested by Mitscherlich's process, but no evidence of phosphorus in the free condition resulted. The acid fluid produced was then tested by Scherer's process, as before, for phosphorus in the oxidised form of phosphorous acid; and the resulting black precipitate oxidised by nitric acid, and tested by a magnesian salt and ammonia. The characteristic crystals of phosphate of ammonia and magnesia were obtained, which proved the existence of phosphide of silver in the black precipitate, which probably arose from the presence of phosphorous acid in the contents of the rectum, cæcum, and colon in small quantity. 6th. The contents of the small intestines were also removed carefully and tested in the same way. Similar results were obtained, viz., the absence of free or combustible phosphorus, but the presence of phosphorous acid. 7th. One portion of the contents of the duodenum was tested by the tincture of iodine, for the presence of starch, but no blue reaction exhibited itself; whereas a reddish port wine colour was exhibited, which appeared to be due to the presence of dextrine, a substance into which starch is converted by digestion. 8th. In another portion of the contents of the small intestines, I endeavoured to destroy the organic matter of the fæces by nitric acid, and expected to find the Prussian blue, colouring matter, but failed in obtaining any. 9th. The whole of the stomach, small and large intestines, were dissolved in the dark by means of hydrochloric acid, absolutely pure; but no luminous appearances were exhibited: these phenomena would have been observed if a certain proportion of inflammable phosphorus had been present; it is a test nearly as good as Mitscherlich's. 10th. The acid solution, filtered from undissolved matters, were tested in a gas evolution bottle and with certain apparatus attached, which enabled me to test at one operation for arseniuretted hydrogen, antimoniurretted hydrogen, sulphuretted and phosphuretted hydrogen. There was negatived evidence of the three former gases, but the black precipitate resulting was proved to be phosphide of silver, and therefore demonstrated the existence of an appreciable quantity of oxidised phosphorus existing in the tissues of the viscera as phosphorous acid; the same product as exists after the phosphorus paste had been exposed to the air. 11th. A large portion of the liver was dissolved and treated in a similar manner, by which a further quantity of phosphide of silver was obtained, from which crystals of phosphate of ammonia and magnesia were obtained, and examined by the microscope. Results: Evidence of the presence of free phosphorus in minute quantity was obtained from the contents of the stomach; whilst evidence of phosphorous acid, the lower oxide of phosphorus, was obtained by Scherer's test, as modified by myself, from the contents of the stomach, and of the large and small intestines; whilst a still larger quantity of the same phosphorous acid was shown to have been absorbed or imbibed by the tissues of the stomach and intestines, and to be present in the liver; whilst the presence of dextrine in the intestinal canal shows that starch had been present there during life. I infer that phosphorus was probably the cause of the acute inflammation of the mucous surface of the stomach and intestines, of which the infant died."

THE COLOURING MATTER OF THE BILE.—In a communication lately made to the Royal Society, Professor Stokes, of Cambridge, has shown that the colouring matter of the bile, which has been named biliverdin, is not, as was supposed by Berzelius, identical with chlorophyll. The optico-chemical tests, unknown, of course, to that great chemist, indicate marked differences between the two substances. Professor Stokes has lately been much engaged in the optico-chemical examination of chlorophyll, and proposes to present the details of these researches to the Royal Society before long.

THE LATE EXAMINATION FOR THE ARMY MEDICAL DEPARTMENT.—As might have been expected, the late desperate attempt to obtain candidates for the vacant Assistant-Surgeoncies in the army has proved an utter failure. Although the bait was thrown far and wide, and any unsettled, unemployed man, possessing the necessary qualification, and being under thirty years of age, was solicited to make application, only fourteen candidates were obtained. Of these three were physically disabled, four were rejected as Professionally incompetent, and the remaining seven were accepted. In the Indian and British armies together there are now nearly two hundred vacancies. When it is too late, the authorities will perhaps become alive to the folly of the course they are pursuing. We can assure them that they will never make the service a popular one, and never obtain an influx of highly-educated Professional gentlemen as candidates, until they grant those reforms in the matters of pay, retirement, position, and duties, which have been so frequently insisted on in this Journal.—'Medical Times and Gazette.'

POOR-LAW MEDICAL REFORM ASSOCIATION.—Mr. Griffin, Weymouth, requests us to inform the Poor-law Medical Officers that in 'Knight's Official Advertiser' of the 15th ult. it is stated:—"The Select Committee on Poor Relief (England) continued to meet on Tuesdays and Fridays until the Easter recess, and have now resumed their sittings. The Members alone are present when the Committee are considering their report, and the resolutions agreed to will not be made known until they are formally reported to the House. In all probability the report will be issued early next month." Since the first of April Mr. Griffin has received the following subscriptions in aid of the funds of the Association:—Jay, F. F., Depwade, 5s.; Davies, F., Pershore, 10s.; Whiteman, R. H., Wandsworth, 5s.; Banks, P. H., Bedford, 5s.; Thomas, J. L., Carmarthen, 2s. 6d.; Stainthorpe, F., Hexham, 5s.; Terry, H. Junr., Hardingstone, 5s.; Percival, W., Hardingstone, 5s.; Spicer, N. W., Chard, 1*l.* 1s.: Morton, S. E., Great Boughton, 10s.; Clarke, J., Barnstaple, 5s.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAY 4.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, MAY 5.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; Great Northern Hospital, King's cross, 2 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopœdic Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Hullah "On Music (1600—1750)."

FRIDAY, MAY 6.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal Institution, 8 p.m.—Mr. J. Scott Russell, "On Gun Cotton."

SATURDAY, MAY 7.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Royal Institution, 3 p.m.—Prof. Frankland, "On Metallic Elements."

MONDAY, MAY 9.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1¼ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAY 10.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

New Observations upon the Structure and Formation of Certain Nervous Centres, tending to prove that the Cells and Fibres of every Nervous Apparatus form an Uninterrupted Circuit. By Lionel S. Beale, M.B., &c. London: John Churchill and Sons.

Glaucoma, and its Cure by Iridectomy. By J. Soelberg Wells, Esq. London: John Churchill and Sons.

Report of the Committee of Visitors of the Lunatic Asylum for the North and East Ridings of Yorkshire.

The Dublin Quarterly Journal of Medical Science, May, 1864. No. LXXIV.

Treatment of Diseases of the Skin. By Dr. W. Frazer. Dublin: Fannin and Co., 41 Grafton street.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

WE regret that we are compelled to postpone until next week the first of a series of papers on "Prostitution," by DEPUTY-INSPECTOR-GENERAL DOLMAGE; together with several other interesting communications, reviews, and articles of news.

A THREE-YEARS' SUBSCRIBER, *Bath.*—A L.R.C.P. Edin. has no *legal* right to prefix Doctor to his name, but custom and courtesy may justify him in doing so.

A MEDICAL STUDENT might apply with safety to the Surgeon of his Hospital, or if he will furnish us with more information we might be able to assist him. We are unwilling, unless under very special circumstances, to recommend particular practitioners.

DR. J. L. E., *Birmingham.*—We believe that the *Laminaria Digitata* may now be procured of the instrument-makers. It is a common sea-weed in Scotland.

THE copy of the 'Edinburgh Evening Courant' has been received, and the subject shall be noticed next week.

DR. DRYSDALE'S letter is in type, and will appear next week.

A CONSTANT READER'S letter shall appear next week.

A SUBSCRIBER.—The paper has been received, and the subject shall be noticed.

A STUDENT'S letter shall be inserted.

DR. TORBOCH'S letter shall appear next week.

Society for Relief of Widows and ORPHANS OF MEDICAL MEN.—INSTITUTED 1788.—Incorporated by Royal Charter, 1864.—The Members are reminded that a QUARTERLY COURT of DIRECTORS will be held on the first day of JUNE next, at which Candidates for Admission into the Society can be proposed. It is desirable that the form of proposal be filled up and forwarded to the Secretary a few days before the Meeting. The Form of Proposal may be obtained of the Secretary. The benefits of the Society are restricted to the Families of deceased Members of not less than two years' standing.

The Secretary attends at the Office every Wednesday and Friday from Four to Five o'clock.

S. W. J. MERRIMAN, M.D., Secretary.

53 Berners street, W., May, 1864.

Society for Relief of Widows and ORPHANS OF MEDICAL MEN.—INSTITUTED 1788.—Incorporated by Royal Charter, 1864.—The Seventy-sixth Anniversary Dinner of this Society will take place on Saturday, the 28th May, at the Albion Tavern, Aldersgate street.—Thomas Arthur Stone Esq., President and Trustee, in the Chair. Tickets one guinea each, to be obtained from the Stewards, from the Secretary, or at the Tavern. Dinner to be on the Table at half-past six o'clock precisely.

Any registered Member of the Medical Profession residing in the county of Middlesex, or within the limits of the London District Post, is eligible as a member of this Society, at a subscription of Two Guineas a year. Widows and Orphans of members of not less than two years' standing are eligible for relief, and to such applicants relief was granted last year to about 2,000*l.*

S. W. J. MERRIMAN, M.D., Secretary.

53 Berners street, W.

The Medical Baths and Fumigations. 40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Baréges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic sease where internal medicines are inadmissible, or have altogether failed effect. Imitations havin g arisen, be particular in the address.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

Brown's Cantharidine Blistering TISSUE, prepared from pure Cantharidine. An elegant preparation, vesicating in much less time than the Emp. Lyttæ, P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent practitioners in the kingdom.—In tin cases, containing ten feet, 6s. 6d.; and small cases of five square feet, 3s. 6d. each.

BROWN'S TISSUE DRESSING.

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, Burns, &c., and may be called a companion to the above.—In tin cases, containing twelve square feet, 1s. 6d. each.

Sole Inventor and Manufacturer, T. B. BROWN, Birmingham. Sold by all Wholesale and Retail Druggists and Medicine Agents throughout the British Empire.

"JUST IMPORTED—THE FINEST OF THIS SEASON."

Pale Newfoundland Cod-Liver OIL and LIGHT-BROWN COD-LIVER OIL, from the Loffoden Islands.—These Oils are of superior qualities and can be confidently recommended to the Profession. The Pale Newfoundland Oil in one gallon bottle and basket included, 16s.; the Light-Brown bottle and basket included, 9s. per gallon. Post office Orders to be made payable to THOMAS KEATING, 79 St. Paul's churchyard, London.

Aloina.—T. and H. Smith, the Dis- coverers of this,

THE CRYSTALLINE PURGATIVE PRINCIPLE OF ALOES, (vide "Edinburgh Monthly Journal of Medical Science" for Feb. 1851,) continue to prepare and supply it. They have the gratification of knowing that the most eminent of the Profession prescribe it, to the exclusion altogether of the various kinds of aloes.

Orders executed direct, or through any Drug House, by T. & H. SMITH and CO., 69, Coleman-street, City, London, and 21 Duke street, Edinburgh

MEDICAL GLASS AND GENERAL FIXTURE WAREHOUSE.

William Hawke, Wild Court, Great WILD ST., DRURY LANE, LONDON, W.C., (late Ansell and Hawke,) Manufacturer of every description of Shop Fittings, Dealer in Medical Glass, Earthenware, and all kinds of Shop Utensils, Medical Labelling, Writing, and Embossing on Glass.

Drawings, Specifications, and Estimates furnished for Fitting-up Druggists, Shops and Surgeries, with every requisite, and for erecting Shop Fronts. Druggists' Stocks and Fixtures valued.

Labels Cut by Machinery.—Adhesive for marking goods, 1s. per 1,000; Dispensing or Chemical, 2d. per 100, kept in stock; with Name and Address, 2s. per 1,000; Mixture, Pill, &c., equally moderate. An assortment of Labels for all trades. Contracts with large consumers.

J. CROSS, & SON, Engravers, Steam Machine Printers, Lithographers, and Stationers, 18 Holborn Hill, E.C. Established 1813.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

BY ROBERT HUNTER SEMPLE, M.D.,

Member of the Royal College of Physicians of London, Senior Physician to the St. Pancras and Northern Dispensary, Physician to the Standard Life Assurance Company.

(Continued from page 260.)

The Morbid Sounds of the Heart, or Murmurs.—It was mentioned in the last communication that all the morbid sounds of the heart might be considered due to *friction*, either of one solid part upon another, or of the blood against a contracted orifice, or against a tumour or excrescence upon a valve; or it might be due to the passage of *unhealthy* blood over healthy solid structures. Thus, a murmur might indicate, according to circumstances, an attack of pericarditis, an obstruction of the valves, regurgitation of the blood through valves insufficiently closed, friction of the blood against projecting growths or tumours, or the passage of unhealthy blood (as in anæmia and chlorosis) through unhealthy valves and vessels. It is also stated that the murmurs may sometimes be due merely to certain abnormal conditions of the nervous system, as hypochondriasis and hysteria, without appreciable disease of the heart or the blood; but I am unable to confirm this statement by my own experience.

Although in a general sense it may be stated that all the murmurs are due to friction, and are, therefore, essentially the same, yet it is indispensable to examine them individually in order to determine their relative importance in the diagnosis of disease. I must also observe that the practitioner, in forming his opinion, ought to take into consideration all the concomitant circumstances of each case; for if he were to judge exclusively by the character of the murmur, he would be liable to fall into as many mistakes as another who should discard the significance of the murmurs altogether, and trust entirely to the rational signs.

Friction Sound—Exocardial Murmur.—In a healthy state, the adjacent surfaces of serous membranes glide over one another without any noise, in consequence of the serous fluid thrown out on their surfaces for the purpose of diminishing friction, on the same principle that oil is applied to the piston-rod and other working parts of a steam-engine. But when the natural serous secretion is dried up, or when lymph is poured out from the contiguous surfaces, then the two sides of the membrane grate against one another, and produce the creaking noise which is heard on the application of the stethoscope, and is known by the name of *friction-sound*. This sound presents various degrees of intensity, being sometimes *soft*, like the rustling of silk; sometimes *rough*, like the creaking of new leather, to which it is indeed compared (*bruit de cuir neuf*); and sometimes *scraping*, like that produced by a rasp. The first sound indicates an effusion of lymph of recent occurrence, soft in consistence, and small in quantity; the second indicates that the effusion is older, thicker, more unequal, and more resisting; and the third, or the scraping sound, is caused by the formation of more hardened morbid products, such as cartilaginous or osseous depositions in the false membranes.

The pericardial friction-sound is the same in character with the friction-sound of the inflamed pleura, and the conditions are the same in both cases, but the morbid sounds are synchronous with the respiratory movements in the one case, and with the movements of the heart in the other. Hence, therefore, arises the diagnostic difference; and it is further to be noticed that in the greater number of cases of pleurisy, the movements of respiration are made with very great pain, and are accompanied with cough; whereas it generally happens that there is no pain complained of by the patient in pericarditis, and it is, therefore, the more necessary to observe the physical signs, which are often the only trustworthy indications of the disease. This pericardial friction-sound is a certain indication of inflammation of the pericardium, and is necessarily only temporary in its duration, and will be modified in proportion to the progress of the disease. It is produced at an early period of the inflammation, when an effusion of albumino-fibrine has taken place, but when the quantity of the effusion is still small. It diminishes in proportion to the increase of the effusion, which of course separates the serous surfaces and prevents them from rubbing together, and it ceases when the fluid is in such quantity as to prevent the contact of the opposite sides of the membrane. It will reappear when the disease begins to abate and the fluid diminishes in quantity, and it will cease quickly if extensive adhesions are rapidly formed, or it will last longer if the adhesions are formed more slowly. The friction-sound, therefore, is necessarily temporary, and can exist only while there is a small quantity of effused fluid on the anterior surface of the heart in the sac of the pericardium.

The exocardial friction-murmur is generally double, while the endocardial murmurs are more frequently single, and the exocardial murmurs are quite independent of the ordinary sounds of the heart. Again, the exocardial murmurs are limited to the præcordial region; while the endocardial are often prolonged into the carotid arteries. But, as I have before remarked, these observations cannot be considered perfectly accurate, and each case must be separately studied, and always in connexion with the concomitant circumstances. The exocardial and the endocardial murmurs are very frequently both present in acute cases, but in chronic cases, the existence of a murmur can only be referred, for reasons already explained, to the existence of disease *within* the heart.

Bellows-sound—Endocardial Murmurs.—These sounds are of various kinds, being sometimes soft and blowing, constituting the true bellows-sound; sometimes rough, like that of a file; and sometimes sharp, like that of a saw. I do not know that these varieties of sound are allied to any definite and distinct pathological conditions of the heart or the blood, and, moreover, the intensity of the sound is by no means necessarily proportionate to the gravity of the disease. Indeed, the contrary is often the case; a very slight obstruction causing a loud murmur, while a serious deviation from the healthy state may produce only a very slight one. It is almost unnecessary to insist, that the presence of a murmur, however slight, is a pathological indication of great importance, although it does not necessarily indicate the presence of a serious disease. Generally speaking, it is a far more significant sign of disease in the male than in the female subject, for in the latter it is very often caused by morbid conditions of the blood, without any appreciable lesion of the heart, and may disappear altogether as the general health improves. It should also be observed, that although a murmur in the male subject may attend serious disease of the heart or the arteries, yet it may be caused solely by the pressure of some gland or tumour over the course of an artery, and will disappear when the pressure is removed. Again, the apex of a tuberculous lung, by pressing upon the subclavian artery, may give rise to a murmur, thus simulating arterial disease.

I am aware that some French authors, as Laennec and Bouillaud, and also Barth and Roger, consider that the rough murmurs, such as the rasp, file, and sawing sounds, indicate a more serious disease than the bellows-sound, and usually indicate a more hardened or osseous state of the valves over which they are heard; but in practice these distinctions cannot be maintained, for the rough sounds are often heard when the valves have undergone no calcareous degeneration, and, on the other hand, a very advanced stage of valvular disease may produce only a bellows-sound.

As an instance of the comparatively slight disease of the heart which may produce a very loud murmur, I may quote the following case, which occurred to Dr. C. J. B. Williams, and is recorded by him in the second volume of the 'London

Journal of Medicine,' 1850:—A man, aged about thirty, was admitted into University College Hospital for a slight ailment, attended with palpitation. The remarkable feature of the case was a very loud musical murmur, of a cooing note, following the second sound; it was most distinct in the mid-sternum, but it was also heard in every part of the chest, in the arteries of the neck, and, although faintly, even in the radial artery at the wrist. The patient was kept in the hospital, not because his health was suffering, but as a kind of stethoscopic curiosity. But it unfortunately happened that he caught typhus fever, which was prevailing at the time, and died in the hospital. On examining the body, the ventricles were found moderately enlarged and thickened, but the valves were all healthy, except the aortic, and the only morbid appearance on them was that one of them had its free margin neatly retroverted, so as to leave a fine, smooth chink for regurgitation.

REMARKS ON PROSTITUTION,

WITH A

VIEW TO THE ADOPTION OF MEASURES

FOR THE

CHECKING OF VENEREAL DISEASES.

By Gideon Dolmage,

Deputy Inspector-General of Army Hospitals, and Medical Attendant to the Small Arms Factory and Military Clothing Depôt, Pimlico.

In the year 1860, in a paper containing "Observations on the Mortality, &c., of the Troops at Aldershot," which I had the honour of submitting to Lieut.-Gen. Knollys, then Commanding Division, Camp Aldershot, I stated, as the following extract will show, that "the average *daily* percentage of sick to strength, for the year 1859, was 5·6; the former being 812, and the latter 14,256; that the number of rheumatic cases treated in the camp may, at first sight, appear large, but that very many of these were not labouring under true rheumatism, a considerable portion being affected with rheumatoid pains, the result of syphilitic constitutional taint; that the great prevalence of venereal disease—the cases numbering for the year 1859, 6,621—was, without doubt, the original cause of many other affections which appear upon the face of the sick returns; that the women infesting the neighbourhood of the camp were lodged in many of the public-houses in its environs, and were of the lowest description; that it would be very desirable, and would tend much to improve the sanitary condition of the camp, at least as far as syphilitic ailments are concerned, if the authorities of the different parishes would prosecute the owners of such public-houses as could be proved to have harboured prostitutes; that this could be done, having obtained evidence from such men as had contracted disease from cohabitation with women in such houses. That, from my experience as an Army Medical Officer, I was lead to the conviction, that four-fifths of the mortality in the British army was owing, directly or indirectly, to syphilis; and that unless some plan were devised to deter soldiers from exposing themselves to such contagion, I feared there could be little diminution in the numbers of those who would become diseased, and scarcely any improvement, on this point, in the sanitary condition of the army."

It is stated in 'The United Service Gazette' of April 9th, 1864:—"From Medical and military returns, we are enabled to show that from one removable cause of sickness alone (namely, syphilis), four or five regiments were permanently disabled from duty; whilst even when the invalids had recovered, so much had their constitutions been injured by the ordeal through which they had passed, that there was nothing left for commanding officers but to discharge them, as unfit for the service."

Many there are who will object to the plans we are about to suggest in this paper, for the alleviation of the great evil which exists amongst us; and, without doubt, the opinions of such objectors are worthy of every respect and deference, because they are held on what is considered to be just grounds, and are honest in their intentions.

But opinions are not arguments; and however just they may seem to the holders of them, however honest they are in purpose, however upright in intention, they cannot be accepted as legitimate or binding, since they offer no means of preventing an origination of the disease, a further spread of it when originated, a staying of the fearful ravages it commits, nor even a tentative effort at eradication—since, in a word, they fail to meet the exigencies of the case. On this account, therefore, they must not be heard with that attention which would exclude from notice propositions that have for their object not so much an eradication as an amelioration.

The lesson taught us by past ages is, that wherever men are collected, especially in large numbers, prostitution will—we had almost said must—exist; now, since we cannot prevent the offence, nor wholly banish the offenders from our camps and our ranks in civil life, we must adopt those means which are actually at our command.

We admire the principles, we reverence, in the highest signification of the word, the tenets of religion upon which are based moral objections to the plans about to be proposed; we bow in sincere and humble adoration before Him who has said "Thou shalt not do evil that good may come;" and we render all holy veneration to this command, which we strenuously contend we are not violating when we urge the adoption of those proposals which we submit for consideration.

Wherever men are aggregated, without the most powerful restraining influences to govern them, the offence which leads to the disease will be committed; nay, more, from our own experience we can state that when men are isolated from the opposite sex, crimes are committed more disgusting and revolting to our nature, and that seem greater violation of Nature's laws, which, however, are not so in reality; but which, physically speaking, reduce the man to greater helplessness, and in a number of instances have apparently degraded him the more morally.

We must not be misunderstood. We are not advocating the crime of fornication; we are not even trying to excuse that we are bound to condemn; we offer no extenuation for its commission, nor any exculpation for those guilty of it, for we are well aware that when the Divine edict went forth against the committal of this act, and so constituted it sin, a power, natural or superhuman, was at the same time given, which, if exercised, would enable the unlawful passions to be ruled and overcome, and those desires to be controlled which, pronounced by a pure and holy Deity to be offensive to Him, are therefore sinful in their indulgence.

It is our duty to fight, not with imaginary positions, but with circumstances as we find them.

We can never, even by the most rigid system of discipline, prevent this crime; not all the restraint of arms, both civil and military, can keep men from pursuing the bent of their desires; unless, indeed, we bind them hand and foot or strengthen their minds with those principles which will make them to abhor the crime at the same time that we impart to them strength to resist its commission. Now, we cannot bind men as we would the veriest malefactors; nor can we impose upon all the constraining influence of religion, since all will not accept it as the rule of their lives.

Moreover, it is our opinion that we cannot *eradicate* this disease from amongst us. We are too well acquainted with human nature to suppose it will cease to err; we know that sin must and will abound, while we retain our present condition, that sin and human nature are inseparable, and that the consequences of sin, as inseparable from the sin itself, are inevitable.

We must deal with this malady in its every bearing as we find it, and must not allow ourselves to be carried away with any Utopian ideas. We find an evil, we trace it to its cause, but we are powerless, utterly powerless, in every sense of the word, to remove either the evil itself or the cause of that evil; it follows, then, as a matter of course,

that we cannot remove the *wages* of this great crime ; and therefore it behoves us to address ourselves, not to that we cannot effect, but to that we can accomplish, namely, the *amelioration* of conditions which actually exist.

"We find," says the 'United Service Gazette' of April 9th, 1864, "that, amongst our rank and file, the existence of an individual with untainted blood is a rarity, and that there are more discharges taking place in consequence of men having been rendered wholly unfit for duty by their profligacy, than from any other causes."

The men so discharged have been for some time under pay, have been fed, clothed, trained for useful purposes by the Government, and that, too, at no small expense ; but just as their training is accomplished and they are prepared by that training for the field and for all the active duties of the soldier, they are rendered unfit for active service, or placed entirely *hors de combat* by the ravages committed upon their health by this disease, or by the effects of treatment and disease combined.

There is one means of propagating this disease which cannot be overlooked, and to which we shall make allusion. Troops are garrisoned in a town ; the members of them become acquainted with the people, and are admitted into social converse with their families ; attachments are formed ; the troops are ordered away to a camp, or to another town ; the young girls, who have become attached to some of the men, leave their homes, their parents, and their friends, to follow the soldier whom they love ; they follow him ; they are denied admission into the camp ; they are cast off by their soldier-lover, or are seduced by him, and then spurned and degraded. In many instances, these poor girls are of such tender years, as to be mere children—children in years, children in experience, but soon to become children of disgrace and of the lowest infamy. Homeless, friendless, houseless, moneyless, betrayed and rejected, seduced and forsaken, perishing from want of food and that good advice which might reclaim them and lead them back into the paths whence they have strayed, they fall into companionship with the utterly abandoned, become an easy prey to vice and every form of corruption, and, giving themselves up to be the devotees of iniquity, they in turn become nuclei for sin and centres of contagion.

(To be continued.)

HOSPITAL REPORTS.

KING'S COLLEGE.

Case I.—Stone in the Bladder ; Lithotomy ; Extraction of the Calculus.—By Mr. Fergusson.

The patient was a strong, well-built man, of middle age, and had suffered severely from calculus which, on examination, proved to be lodged in the back part of the urethra, immediately in front of the neck of the bladder. From the appearance it presented, as seen after its removal, it was probably of prostatic origin, that part of it which was imbedded in the gland being, in composition, oxalic acid, while that projecting into the urethra was coated with uric acid.

Mr. Fergusson, in his remarks upon the case subsequent to the operation, pointed out the clinical fact, that calculi such as these may remain for some time in their position without occasioning any serious distress or uneasiness ; but that, as had happened in one case he witnessed, when the stone is dislodged and pushed back into the bladder, it sometimes creates such irritation, inflammation, and consequent retention of urine, as to demand immediate operative measures for the relief of all these urgent symptoms.

The operation put in practice in the present instance was the ordinary one for the extraction of the calculus by the lateral method ; but we shall not here describe the steps of the proceeding, since they are to be found in Mr. Fergusson's work 'On Operative Surgery.'

In the present instance, the stone, in sounding, had been pushed from its place back into the bladder, whence it was removed ; it was of small size, and illustrated the deceptiveness, as to size, of a calculus when it is placed in such a manner as this was. The contact of instruments with the stone had conveyed the idea of its being larger than it was in reality.

Case II.—Cleft in the Soft Palate, attended with Slight Deficiency of the Hard.

This kind of deformity usually exists when the split in the soft curtain of the palate is situated in the mesian line, and is very difficult to treat successfully, the opening being obstinate in closing, and sometimes altogether opposing the best-directed efforts. Mr. Fergusson, in order to deaden the sensibility of these delicate parts, advises that for some days previous to the operation they should be accustomed to the contact of the finger or other foreign bodies ; by this the irritability is very much lessened, and the operation performed with comparative ease. When the patient is steady, we can then pare off the entire margin of the fissure, which is a much better plan of removal than taking it away piecemeal. The operation, Mr. Fergusson observed, is much more difficult of performance than at first sight it would appear to be, the parts being so bloody, so sensitive, so slippery, and, from their situation, so difficult to bring into proper view, or expose to a good light.

Case III.—Disease of the Hip occurring in a Middle-aged Man.

The subject of this affection was a middle-aged man, of stout and somewhat plethoric habit, and of a florid complexion. The disease had existed for some time and had occasioned a constant discharge of matter for a number of years, yet without any apparent deterioration of the patient's health ; it was evidently of an inflammatory character, had caused an arrest in the development of the leg, and had left a number of sinuses remaining, the openings of some of which could be seen in the inferior and lateral part of the abdomen, about the crest of the right ilium, which was the bone diseased. The sinuses above and below the crista ilii having been enlarged so as to admit the fingers, Mr. Fergusson introduced the index-finger of each hand to ascertain if the dead bone was loose ; but as it did not seem to be, he thought it advisable merely to plug the wounds with oiled lint.

Case IV.—Necrosis of the Humerus, the Result of Fracture.

About last Christmas, this patient had sustained a fracture of the humerus, near the elbow joint, and which was followed by inflammation of the joint. It was difficult to find out whether the bone was loose, though there was no doubt whatever of its being diseased, and that the nature of the disease was deep necrosis of the lower end of the humerus. Having enlarged the sinus which led down to the joint, Mr. Fergusson separated the dead from the living bone by means of, first, the cutting bone pliers, and then of the small bone saw, the fleshy portions of the arm, which retained the bone to be removed, being finally cut across with a scalpel. The wound was stuffed with lint, and the plugging was maintained *in situ* by the turns of an ordinary bandage.

Case V.—Congenital Hernia. Operation for Radical Cure.

The patient was a young child, but being perfectly healthy, its age did not present any contraindication to the operation ; Mr. Wood accordingly operated for the radical cure, using the needles for the purpose of bringing the walls of the canal together. In his remarks, he mentioned a case which he afterwards showed us in the ward : it was that of a little child, who, having been operated on in the usual manner for scrotal hernia, had been affected with a return of the protrusion, the intestine slipping down behind the cord and also behind the tissues, which had been matted together by the inflammation attendant upon the operation. Finding that his first operation did not arrest the descent of the bowel, Mr. Wood performed a second, in which he took up the posterior wall, and united it to the other tissues so completely as to fill in the canal and prevent any further slipping down of the bowel. This measure had been attended with complete success, and the malformation was remedied

REVIEW OF BOOKS.

On the Nature, Pathology, and Treatment of Puerperal Convulsions. By Richard Hodges, M.D., F.R.C.S. Pp. 96. London: Churchill and Sons. 1864.

Dr. Hodges, having been extensively engaged in the practice of Midwifery for the last twenty years, has considered it to be his duty to contribute some of the results of his experience to his professional brethren, and he has chosen the subject of puerperal convulsions, in the treatment of which formidable disease he informs us that his success has been very great. He describes first the symptoms, diagnosis, and prognosis of the disease; next, the causes which originate it; then its pathology, and lastly its treatment. All these topics are ably handled, and Dr. Hodges proves himself to be well acquainted with the literature of this affection, as well as with its practical management; but, nevertheless, we do not find that he has introduced any novelty into his pages or presented us with any striking features of originality in the design or execution of his treatise. His chief aim appears to be to inculcate the necessity of early and copious blood-letting as the sheet-anchor on which the practitioner ought to rely in the treatment of puerperal convulsions, and it is probable that most obstetricians will be disposed to agree with him, except those who now maintain that venesection ought never to be employed at all. Out of twenty cases alluded to by Dr. Hodges, seventeen recovered, and in all of these, bleeding was early and efficiently, though cautiously practised; and of the three fatal cases, in one, bleeding was not performed at all, in a second, it appears to have been performed too late, and the third case sank from peritonitis and ruptured uterus. Whether the experience of Dr. Hodges in the treatment of this disease is sufficiently extensive to give due weight to his precepts, may perhaps be doubtful, but his book is written in an earnest style, and contains nothing that is objectionable.

New Observations upon the Structure and Formation of Certain Nervous Centres, tending to prove that the Cells and Fibres of every Nervous Apparatus form an Uninterrupted Circuit. By Lionel S. Beale, M.B., F.R.S., Professor of Physiology and of General and Morbid Anatomy in King's College, London, &c. London: Churchill and Sons. 1864.

This memoir, which is reprinted from the second part of the 'Philosophical Transactions for 1863," is intended to clear up some disputed points in reference to the structure of certain portions of the nervous system. The ultimate composition of nervous matter being divisible into cells and fibres, it has been hitherto maintained that there are three classes of cells, some being unipolar, others multipolar, and others apolar, or, in other words, that some have one fibre in connexion with them, others several fibres, and others none at all. But Dr. Beale is compelled to conclude from his recent researches, made upon different animals, from the mammalia down to the annelida, that every nerve cell, central or peripheral, has at least two fibres in connexion with it, and that therefore there are no apolar and no unipolar cells in any part of the nervous system. The whole subject belongs, of course, to the region of transcendental anatomy, but it is unnecessary to inform medical readers that investigations such as these often throw a new and unexpected light upon the nature of vital actions and upon the phenomena of disease, and are therefore worthy of the deepest attention. Dr. Beale's memoir is accompanied by numerous plates, illustrative of his microscopical discoveries, which have, in the present instance, been made in the nerve-structures of the frog and the *hyla arborea*, but which are probably analogous or identical with those which may be demonstrated in the case of other animals.

Coxeter's Catalogue of Surgical Instruments and Apparatus. Second Edition.

The Second Edition of Mr. Coxeter's Catalogue is much enlarged as compared with the first edition, and the woodcuts are increased to the number of two hundred. The book now includes not only the usual instruments employed in operative surgery, but all the appliances recommended or used by physicians and surgeons in the treatment of disease, or injury; together with information, conveyed in the form of notes, as to the application of the various articles described or depicted. The lists are arranged under their various heads, with the prices affixed to each, the names being given of the inventors of the different instruments, and there is an index for reference at the end. Practitioners at a distance will find in these pages a kind of *résumé* of the improvements made in later days in the instrumental department of the Profession, and the numerous illustrations will at once present to the eye the design and object of each article in a far better manner than any mere description could afford.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 5 AND 19.

MR. PRESCOTT HEWETT, President.

DR. WALE HICKS read a report on a

SPECIMEN OF LUNG AND SPLEEN OF A HORSE

obtained at the Veterinary College, and mentioned in our last report. The spleen was seen to be almost filled with nodules of tolerably firm yellowish white tissue, the larger nodules being about two inches in diameter, and the smaller about a quarter of an inch. The lung was affected much in the same way, but the masses were greyish white, less firm, and more juicy, and many of them were very minute. Portions, both of the lung and spleen, were removed for microscopic examination. On making thin sections of the lung tissue, and washing and pressing them, portions of the infiltrated substance were removed, and many of the air-cells could be distinctly seen, empty and healthy-looking, which were before entirely blocked up. The matter contained in the air cavities, however, was not so easily or so completely removable as in the specimen of horse's lung before examined. The cell-growth somewhat resembled that in the previous specimen, but was more varied. Most of the corpuscles had a finely granular appearance, and some of them contained a number of distinct minute globules resembling oil globules. A considerable number of the corpuscles were small and rounded, about the size of a blood corpuscle; a smaller number were much larger, double or treble the diameter of the former, also spherical, and containing a distinct nucleus. Besides these, there were many other corpuscles intermediate in size, varying greatly in shape, some oval or rounded, others fusiform or candate; most of these were also nucleated. Some of the juice from the cancerous nodules of the spleen was also examined, and found to resemble greatly that from the lung, the chief difference being that the cells were somewhat less distinct and well formed, and were mingled with some of the elongated fusiform fibre-cells of the spleen, and with a greater quantity of granular matter than was observed in the lung.

Dr. GIBB read a report on Dr. Murchison's case of

NECROSIS OF THE HYOID BONE.

The specimens submitted to him, after the most careful examination and comparison with a number of healthy bones, were made out to be component parts of a necrosed hyoid bone. The larger specimen consisted of the right half of the body of the bone, being much thicker than natural, the result of the morbid process, which most probably was in the first instance periosteal, and extending to the true osseous structure. The anterior projecting angles for the origin of muscles corresponded pretty accurately with those of the healthy bone. The smaller specimen was a portion of one of the greater cornua, probably the right, as the general disease would seem to have been mainly confined to that side. Dr. Gibb thought that, allowing for the alterations produced by inflammation, the diagnosis of the bone involved was most satisfactorily established.

Dr. SCHULHOF showed several

FIBRINOUS CASTS OF THE UTERUS.

A woman, 62 years of age, who had had good health until recently, began to suffer from a sanguineous discharge, and subsequently passed two substances analogous to the amenorrhœal membrane of younger women.

The specimens were referred to Dr. Graily Hewitt for further examination.

Mr. SQUIRE then showed the

OVA OF THE PEDICULUS CORPORIS.

They had been taken from a man, 60 years of age, who had suffered from prurigo two years. He said that the body louse was a frequent cause of the disease called prurigo senilis. It was not often found, as it was not looked for in the right place, viz., in the clothes. Mr. Squire had examined sixteen cases, and had found the lice in each.

Dr. BRISTOWE could confirm Mr. Squire's statements as to the lice being a frequent cause of prurigo senilis.

Dr. HARLEY showed a specimen of

CONGENITAL MALFORMATION OF THE KIDNEY.

A child died at the age of 10 months of croup, having had no symptom of renal disease. Her only peculiarity was that she would never lie on the right side. There was no kidney stricture to be seen, the ureter was quite occluded, and a mass of cysts occupied the site of the kidney.

Dr. GIBB exhibited some

WORMS EXPELLED FROM THE NOSE AND FRONTAL SINUSES

of a girl, aged 11 years. For three months she complained of pains in her head and over the frontal sinuses, and also in the chest. The face, forehead, and nose then became swollen and erysipelatous, with a discharge from the nose and the passage of several worms, which were believed to come from the frontal sinuses. They were exceedingly small, about an inch long, and when coiled up were not larger than pins' heads. The girl is still under treatment in the Westminster Hospital.

Mr. MASON inquired if Dr. Gibb had seen any of the worms passed.

Dr. GIBB had seen them come from the right nostril.

Dr. OGLE exhibited

A CHILD HAVING THE GREATER PART OF THE STOMACH, DUODENUM, AND ALL THE INTESTINES EXTERNALLY LYING ON THE OUTER SURFACE OF THE ABDOMEN—ILLUSTRATED BY PHOTOGRAPHIC REPRESENTATIONS.

For the opportunity of exhibiting this specimen Dr. Ogle was indebted to Mr. James Eaton, of Grantham, formerly a student at St. George's Hospital. The child (a male) was apparently an eight months' child, and was born alive. The mother, in good health, aged 23, had a natural and very easy labour, and the liquor amnii had escaped before medical aid could be obtained. The child breathed freely at first, but after a few hours began to breathe heavily. The exposed stomach and bowels became inflated and inflamed, after two evacuations of meconium. On the following day the breathing had become laborious, and the viscera more distended. There was also much crying, as if pain was suffered. The child died twenty-nine hours after birth. The viscera, situated externally, were quite devoid of any peritoneal investment, and communicated with the abdominal cavity by means of an opening of the size of a shilling in the abdominal parietes, about an inch from the umbilicus. When the intestines, &c., were drawn on one side, the liver within the abdomen could be seen through the above-mentioned opening. The peritoneum lining the abdominal walls was found to be directly continuous with the outer skin at the forementioned opening in the abdominal parietes. No other maldisposition of parts was found in the body.

Dr. OGLE also exhibited a specimen of

COLLOID OR ALVEOLAR CANCER OF THE PERITONEUM OF VERY RAPID GROWTH.

The patient, a women aged 47, was admitted into St. George's Hospital, under Dr. Ogle's care, in September in last year. She had only been ill between seven and eight weeks, suffering at first from anasarca of the legs; frequent vomiting and constipation followed (but never jaundice), and she was admitted with constant vomiting of a greenish fluid, and pain chiefly at the right side of the epigastric region. The urine was free from albumen. Much pain came on over the belly, which had become distended with fluid, and irregular, hard masses became felt in the abdomen, especially in the right cæcal region. The pulse was mostly very quick (about 112 in a minute). She sank and died two weeks after admission, and about ten weeks after the first symptoms set in (her mind remaining entire to the last). After death the entire peritoneum was found studded with numbers of colloid carcinomatous growths, forming a continuous layer, and the great omentum formed a large mass of the same growth. Moreover, the pylorus of the stomach was thickened by a growth of a distinctly *scirrhous* nature.

(To be continued.)

THE HARVEIAN SOCIETY, APRIL 7, 1864.

PRESIDENT—WILLIAM ADAMS, ESQ., F.R.C.S., in the Chair.

The PRESIDENT exhibited casts of the knee-joints of a young gentleman aged ten, one of which showed a complete dislocation of the patella outwards. There was no knock knee. Some years ago, the boy met with an accident whilst playing, and since then he had been unable to engage in play; indeed, his parents dreaded his going out, as he was apt to fall and dislocate the patella. Mr. Adams stated that he intended to bring about partial anchylosis of the joint by keeping the limb motionless in the straight position, and he hoped that in eighteen months or so there would be a stiff joint.

DIPHTHERIA.

Dr. CLEVELAND had lately had two cases of diphtheria, which recovered under a stimulating treatment, and sponging the fauces with a solution of borax.

Dr. GRAILY HEWITT had, in the cases of diphtheria which had recently come under his care, observed that the patches of effusion occurred at a somewhat advanced stage of the disease, often out of sight of an ordinary inspection of the fauces. The upper part of the pharynx above the uvula or the posterior nares was the primary seat of the disease in some cases. A discharge from the anterior nares was one of the earliest symptoms. He had observed great benefit to result from topical applications, made by means of a piece of cotton wool, dipped in an astringent fluid, and tied to the end of the finger to the upper part of the pharynx; stimulants were quite necessary, and nourishing diet frequently administered.

Dr. GREENHOW considered topical applications as of no great importance in the treatment of diphtheria. Of fifteen post-mortems made by him in cases of diphtheria, he had found that the mischief was by no means confined to the surface of the diseased parts, but extended deeply into the tissues beneath. The membranes approached the condition of sloughing, and abscess is sometimes found in the centre of the tonsil. Sometimes there is ecchymosis into the muscles of the neck. Any violent local means are, indeed, counter-indicated, and deodorants alone are of service. The medication to be preferred when hæmorrhage ensues is the tinct. ferri sesquichlor.; it penetrates through the membrane. For his own part, he had renounced local medication, such as nitric acid, and had seen cases where strong applications had done much mischief. He mentioned the case of a lady, who, six weeks after the disease, was unable to move her tongue. Her hands and legs became quite powerless also. She was, however, recovering under the administration of cold affusions.

Dr. FULLER observed that it was important to ask ourselves, What is the nature of diphtheria? In itself, a patch of membrane on the pharynx is of no great consequence, and patients died when no such patch was seen, as happened in the case of a child who died in St. George's Hospital. Patients die poisoned, and tearing off pieces of the membrane does no good. Entire rest is absolutely required, and the mere sponging out the fauces will sometimes destroy the child. By following out this rule he had not lost a case for five years. Iron, quinine wine, and chlorate of potash were the best internal remedies.

Dr. HARE quite agreed that topical applications are worse than useless in diphtheria, except when the discharge is very fetid. In this case a lotion containing Condy's fluid may be snuffed up the nostrils with advantage.

Dr. COCK observed that some disinfectant ought to be placed in the utensil used for spitting into by the patient.

A paper was read by WEEDEN COOKE, ESQ.,

ON THE TUMOURS AFFECTING THE FEMALE BREAST.

Dividing these tumours into the solid and the cystic, the author explained the methods of diagnosis by manipulation and by the grooved needle, and related cases of unilocular cystic tumours treated successfully by iodine injections. He then referred to multilocular cysts, which grow to an enormous size, and advised excision, stating that these tumours yield the best results to the knife of any of those which affect the mamma. The proliferous cysts are those within whose walls solid matter is developed, which eventually fills the space previously occupied by serum. Mr. Cooke regards these as undoubtedly cancerous, which will return after excision. He then spoke of the cysts that are sometimes formed in the substance of a scirrhous tumour, and considered *this* change indicative of rapid growth of the decayed mass. It is in this form of tumour that spontaneous evolution of the disease by sloughing most frequently takes place, and when it happens, if the constitution can be supported, cicatrisation may be obtained and the disease remains in abe yance for a very long period. Stimulating injections into the cysts will sometimes bring about the process of evolution. Solid tumours of the breast may be either simple or malignant. The results of common inflammation may be sometimes so severe and lasting, that doubts may readily arise as to the true nature of the swelling. In the first place, age has much weight on the question of diagnosis, inasmuch as cancer does not make its appearance generally during the child-bearing period. The induration of simple inflammation is more diffused than in cancer, neither is there that strong hardness so characteristic of scirrhous tumour; the pain in cancer is sharp and plunging; in simple induration it is constant and wearying. Cases showing that these distinct diseases are sometimes confounded were selected. Induration, the effect of injury, was then referred to, and the points of difference and the results of treatment shown. The adenoid tumour, or adenocele, is an hypertrophy of the absorbent glands, frequently found in the neighbourhood of the mammary glands, and not unfrequently mistaken for enlargement of the mammary gland itself. It is generally found in very slender persons, and in those who have an hereditary tendency to phthisis. These tumours sometimes attain the size of an orange, are exquisitely tender, very moveable, and unattached to the skin or subjacent muscle. They are, when removed by operation, found to be enclosed in an inverting capsule. Covered by a soft piece of leather to shield them from irritation, and the constitution being improved by iron and cod-liver oil, these tumours will frequently disappear; but it occasionally happens that a further degeneration ensues, and the adenoid tumour becomes cancerous.

Two sisters were spoken of who had hereditary phthisical constitutions. Both had adenoid tumours in the breast for many years, and in one, cancer had developed itself within the last two years. From this, and various other experiences, Mr. Cooke disputes the doctrine that an innocent tumour is innocent to the end, and a malignant one malignant from the beginning. He also believed that phthisis and cancer are but different expressions of a common hereditary dyscrasia; the first showing itself principally at the commencement of life, and especially at the catamenial period, and the last cropping out gradually at the cessation of this periodical salutary and sanitary efflux. The author then passed on to describe cancer itself in its various forms, as affecting the female breast. After minutely describing the progress of a scirrhous tumour, he asked and answered some important questions connected with this lesion. Is it derived from an hereditary predisposition? Is it a constitutional or a local disease? Is it capable of being caused by an injury? Are the married or celibate most prone to it? Has suckling or the avoidance of this maternal duty any influence on its development? Has the menstrual cessation any influence it? Is it possible that tubercle and cancer may have the same origin? After considering these various questions, Mr. Cooke went on to describe how the system purged itself of cancer—first, by spontaneous sloughing out of the whole tumour, and, secondly, by a gradual atrophy. In reference to the question of operation, the author states that each case is to be studied for itself; the moral as well as the physical condition of the patient requires a careful analysis. Statistics are not favourable to operation, and if they were, would be an unsafe guide taken alone. The medullary form of cancer in the breast was then described, and in connection with this the comparative value of the various deodorizing substances was discussed. A chlorine wash, made by adding hydrochloric acid to chlorate of potash, Mr. Cooke had found the most efficient, and next to this the permanganates. The hydrocarbons, including the carbolic acid, come next in value, and then the charcoal and carrot poultices; but each might, at times, be substituted for the other with advantage.

Mr. DE MERIC observed, that all that fell from Mr. Cooke on the question of cancer was most valuable, as that gentleman had had so vast a field of observation of the disease of which he had so ably treated. The question which patients most desire to have answered when affected with mammary tumour was, whether such a tumour is cancerous or not. His opinion of cancer was, that it was, like diphtheria, a disease of the whole system; but as to whether cancer was connected with phthisis or not, he was unprepared to say. A woman, age 52, had cancer of the breast. She had lost a daughter four years ago, by phthisis. In this case the cancer seemed to act more like a foreign body in the breast, than like an ordinary cancer. The skin became distended, and at last reddened, and then the destructive process and effusion commenced, terminating in ulceration. At an early stage of the tumour there was a lardaceous hardness of the arm. The whole arm ran into rapid destruction and mortification.

Mr. ADAMS remarked that he had not seen anything to make him believe that simple tumours might turn into cancerous growths. There was no microscopic form of cell indicative of cancer, but still the microscope had done a great deal. It had helped to group together different varieties of tumours. Thus, one group, which Astley Cooper and others regarded as hopeless—namely, fungus hæmatodes—the microscope had shown not to be malignant. The large gourd tumours are of the cystic class. They exhaust by bleeding; but post-mortem examination does not disclose any internal cancer. He instanced a lady at Richmond, who, in 1844, was operated on by Mr. Travers. Liston, Stanley, and the older surgeons had thought the operation unsuitable, and refused it. The lady had, however, insisted, and is now alive. The removal of cancerous growths will sometimes, by removing fœtor, render death less horrible, and may, sometimes, prolong life.

Dr. POLLOCK remarked upon the possibility of the same diathesis developing itself into tubercle and cancer; he was inclined to agree that this might be so. He recollected cases where cancerous parents had phthisical children, and the diseases occur simultaneously in the same individuals, as he had shown in papers read before the Pathological Society.

Dr. GREENHOW remarked that cancer sometimes occurs in growing persons, while, again, phthisis occurs at even advanced ages. E. G., a patient of his, age 65, had phthisis, which he had at first believed to be cancer of the apices of the lungs.

Dr. HARE remarked that the extreme frequency of phthisis pulmonalis made it difficult to judge of its hereditary connection with cancer. Tubercle and cancer very rarely concur in the same individual, and cancerous parents often have cancerous children.

Mr. COOKE replied by thanking those who agreed and those who opposed his views. He had so frequently seen examples of phthisical children being the offspring of cancerous parents, that he must adhere to his opinion of the great affinity of the diseases. He had also seen, in

many cases, strumous glands turn into cancers, and thought they ought to be removed. As to excision of true cancer, if the cancer is left alone, the patients will sometimes live for fourteen or fifteen years, whilst, if the cancer is excised, they will speedily die.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

MR. I. B. BROWN continues his clinical lectures "On the Diseases of Women, remediable by Operation," his present subject being the treatment of prolapsus of the uterus, bladder, and rectum, attended with rupture of the perinæum, which may be *simple*, *extended*, or *complete* rupture. These different forms require different operations, but the principle is the same in all, and consists in restoring the perinæum, by cutting out portions from the sides of the vagina, and bringing together the cut edges by means of sutures. Mr. Brown describes and illustrates the different steps of the operation, and the treatment to be adopted before and afterwards. It is essential, after the operation, to leave the parts at rest for some time, to administer opium, and to support the strength of the patient.——DR. EDWARD SMITH continues his papers "On Dietary in Disease," his present subject being the treatment of obesity. Dr. Smith condemns the indiscriminate attempts sometimes made in the present day to reduce the bulk of the body without inquiry as to the cause and nature of the enlargement; and he points out that there are two classes of obesity or apparent obesity, namely, one consisting of enlargement of the abdomen only, and another of general deposition of fat over the whole body. The attempt sometimes made to diminish the former, by injudicious treatment, may not only fail in its object, but produce serious disease, because this kind of enlargement may be due chiefly to flatulence, and distension of the bowels with effete semi-solid matters. These cases should be treated by purgatives and gentle exercise.

THE 'MEDICAL TIMES AND GAZETTE.'

PROFESSOR HELMHOLTZ continues his very learned and able lectures "On the Conservation of Energy," his subject being now the physiological actions of living bodies.——DR. W. O. PRIESTLEY contributes "A Clinical Lecture on Flexions and Versions of the Unimpregnated Uterus." When these displacements arise from some morbid condition of the uterus or ovaries, appropriate treatment must be adopted for the cure of those affections; when the displacements are unconnected with uterine disease, the case often requires no treatment at all, and may be left to itself. But it sometimes happens that the displacement is the source of serious inconvenience, and cannot be rectified by ordinary means, and then some mechanical assistance becomes necessary. Dr. Priestley describes various kinds of apparatus which have been recommended for rectifying the mal-positions of the uterus, and in some of them there is a stem which passes into the uterine cavity and is retained there. There is a great objection, however, to such instruments, as they irritate the uterus; but Dr. Priestley describes a kind of pessary for cases of retroflexion, having a wire frame-work, which passes behind the cervix uteri and raises the fundus and keeps it upright.——DR. J. W. OGLE continues his "Cases of Softening of the Brain and Spinal Cord," describing the symptoms observed during life and the post-mortem appearances in several patients.——MR. F. A. BULLEY relates "A Case of Inflammation and Gangrene of the Thigh," which terminated fatally, but in which no post-mortem examination was allowed. Mr. Bulley believes, however, that it was a case in which there had existed on the mitral or aortic valves some morbid vegetation, which, being carried by embolism into the circulation, had accidentally made its way into the profunda artery of the thigh, and there caused obstruction, followed by mortification of the corresponding limb.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS, MAY 5TH.

THE ARMY ESTIMATES: ARMY MEDICAL OFFICERS.

On the vote of 262,216*l.* (less by 2,000 than was originally proposed) for defraying the expense of the medical department of the army,

Colonel North called attention to the present inefficient state of the medical department of the army, and observed that, so far from carrying out the recommendations of the committee of 1858, in favour of having one surgeon and two assistant-surgeons to every regiment, there were no less than 200 medical vacancies in the army. The hon. and gallant member referred to the evidence of the Commander-in-Chief, Sir Richard Airey, and other experienced officers of distinction, to show the necessity of having the medical staff of the army increased; but such was the state of things at present, that, although there were 200 vacancies, medical students could not be induced to enter the service.

General Peel said that one of his first official acts when Secretary for War was to issue a medical minute founded on the recommendations of the committee which sat in that year; and he had had the satisfaction of being told by Sir Benjamin Brodie that the effect of the minute was to induce some of the best medical students to enter the army. But he had heard that some of the students who had entered the army under the warrant of 1858 complained that faith had been broken with them; and one of the reasons given for the change was that the Administration had found some difficulty in carrying out the minute. He hoped the noble lord would be able to offer some explanation for the change which had taken place, and for the difficulty of obtaining medical students to fill the vacancies now existing.

Mr. O'Reilly could bear his personal testimony to the good effects of the minute issued by the right hon. and gallant member opposite in 1858, and he trusted the War Department would see the expediency of acting up to the conditions of that minute.

The Marquis of Hartington admitted that there was considerable difficulty in obtaining a proper supply of medical officers for the army, but he could not allow that that was owing to the provisions of the warrant to which the gallant colonel (North) had alluded not having been carried into effect. On the contrary, those provisions had been very fairly given effect to. He was afraid that if the deficiency was to be met, it must be through the House of Commons granting increased remuneration to the medical officers of the army.

Colonel North said that the army medical officers only wished to be entitled to retire after twenty years' service, and he thought this was no more than just. The fact that there were now 200 vacancies in the military service showed that the present system did not attract a sufficient number of competent men. If war was to break out to-morrow, what should we do? A committee which sat eight years ago reported that each regiment in the service should have a surgeon and two assistant-surgeons; but at present the regiments serving at home had no assistant-surgeons at all.

THE MEDICAL CIRCULAR.

WEDNESDAY, MAY 18, 1864.

TRIAL FOR ALLEGED POISONING BY CAYENNE PEPPER.

A trial which took place on Wednesday last at the Central Criminal Court displays in a very remarkable manner the feelings existing in the public mind at the present moment on the subject of illegitimate Medical practice. The case was that of a person practising somewhere in Whitechapel, who was charged with administering to a lad of fifteen a quantity of improper and dangerous medicines, whereby death was caused, thereby rendering the accused liable to trial for manslaughter. It appeared that the prisoner, who possessed no Medical qualification, but called himself a Medical botanist, attended medically in a case described as one of acute inflammation of the hip-joint, and administered a number of powders containing cayenne pepper. The result was that the boy became worse, and died in a few days; and on a post-mortem examination, it was found that all the organs essential to life were free from natural disease, but the hip-joint was in a diseased state arising from acute inflammation, and the stomach was also in a state of acute inflammation and contained a quantity of cayenne pepper. Dr. Letheby, who examined the contents of the stomach, stated, in answer to a question by the Court, that the cayenne pepper given to the deceased had caused inflammation, which had resulted in great exhaustion, ending in death.

Now, as no evidence was adduced on the other side, we may assume that the facts thus set forth were truly related, and that the opinions advanced were entitled to respect. It therefore would appear that a case was made out against the prisoner of having caused the death of this unfortunate youth; not, indeed, by having wilfully and knowingly destroyed him, because such a charge would have amounted to murder, but by having brought about the event by the incautious and improper administration of drugs, of the properties of which he knew little, for the cure of diseases of which it does not appear that he knew anything at all.

The jury, however, thought otherwise, and, without going through the farce of a consultation, almost immediately acquitted the prisoner; and we are told in the papers that the announcement was received with applause and clapping of hands, and no doubt the victim of Medical persecution, as he was styled by his counsel, was conveyed home in triumph by his friends. We only wonder that some of the newspapers have not improved the occasion by joining in the applause manifested by the Old Bailey audience, and by pointing out how important it is to the liberty of the subject, and essential to the welfare of the community, that empirical practice should be defended and encouraged by the law, and that persons should be allowed to destroy the lives of their fellow-creatures without any let or hindrance.

We have no intention of making any lengthened comments upon this wretched caricature of justice, the more especially as we have no wish to be supposed as joining in any persecution of the Whitechapel "botanist." But, perhaps, it will afford some amusement, though of a somewhat dismal kind, to quote a few passages from the speech of Mr. Serjeant Ballantine, as showing the kind of rubbish which, in the absence of anything like sense, or reason, or evidence, often carries weight with a "British Jury":—

"He commenced by observing that it was a somewhat hard thing to see the prisoner standing in the dock *simply because he was not possessed of the ordinary certificate which qualified medical practitioners.* There was a strong feeling of jealousy in the minds of medical practitioners against what they denominated 'quackery,' and *it was in consequence of that feeling that the prisoner had been hunted down by the profession.* The whole question in the case was one of opinion. Medical practice of late years had undergone a complete revolution. Homœopathy had taken the place of blood-letting. The truth was, that every great invention had been received in a spirit of stern and unrelenting opposition. *Jenner, for instance, had been hunted to death for having recommended vaccination as a preventive of small-pox.* The immense sale of pills and ointments in the present day was without a parallel, and yet the doctors would tell the world that these pills and ointments were valueless. *It was beyond all doubt that metallic medicines were injurious, and that vegetable medicines alone should be administered.* At all events, Dr. Coffin was strongly of that opinion, and accordingly he had substituted capsicum or cayenne pepper for the cure of certain disorders; and the question was, whether the prisoner, as a disciple of Dr. Coffin, had either by negligence or ignorance produced the death. The prisoner contended now, as always, that he had committed no mistake, and that *the remedies he applied were the true and proper ones, and his judgment was founded upon experience.* If the prisoner was in error in selling capsicum, then Savory and Moore and every other patent medicine vendor in the kingdom were liable to be indicted. The evidence was most conflicting. Dr. Gant and Dr. Cumming differed wide as the poles asunder; and if the one was a goose so was the other also. (A laugh.) The jury should not be tied to the chariot wheels of any medical man, but they should carefully consider the modest opinions given on one occasion by Sir Benjamin Brodie, rather than the bold, positive statements of the medical men examined that day. So because the prisoner did honestly, and truly, and faithfully administer what he believed to be an efficacious medicine, he was standing where Courvoisier and Palmer had stood before, on a charge of the gravest magnitude. Did the prisoner visit the boy for fee and reward? Certainly not. His was the visit of the Samaritan to the house of poverty and sickness. And was the unfortunate prisoner to be hunted to death because he sold Dr. Coffin's pills, handled a pestle and mortar not according to the most approved fashion of the *Pharmacopœia*, and had the hardihood to poach upon the common of the men who carried in their pockets all the diplomas under the sun? But numbers of persons would everywhere be found who would asseverate in the strongest terms that Holloway's and Morrison's pills and ointment had absolutely cured them of coughs, colds, and rheumatisms, and in one case he believed the advocates of these specifics had gone so far as to declare that Holloway's ointment had replaced a pair of legs. (Great laughter.) The learned serjeant concluded by entreating the jury to rescue the prisoner from what must be considered *by all impartial men as a grave persecution.*"

We are almost ashamed of quoting this trash, in which it is hard to say whether the false reasoning or the falsification of facts is the most apparent. Jenner was *not* hunted to death for inventing vaccination, but received a large sum of money from the British Parliament as an acknow-

ledgment of the boon he had conferred on humanity. The prisoner did *not* visit the deceased like the good Samaritan (although this would have made no difference in the merits of the case), but received money for his visits and medicines. The prisoner did *not* stand in the dock simply because he was not possessed of a medical qualification, but because he had ignorantly and carelessly administered an improper and dangerous drug, whereby death had been caused.

The false reasoning is equally palpable. It is *not* beyond all doubt that metallic medicines are injurious, for iron is not a poison, and strychnia and morphia *are* poisons. The prisoner was *not* indicted for selling capsicum, which of course any grocer might have done, but for prescribing and administering cayenne pepper in a medical case for gain and reward, without knowing its effects on the human body.

As to the bad taste of the whole speech we need say nothing, nor of the feeling which could convert an inquiry into the death of a fellow-creature from the tortures of inflamed bowels into the occasion for the display of tomfoolery, which seems to have been received with shouts of laughter by the brutal and ignorant audience before whom it was made. But it is needless to add anything more. No doubt Mr. Serjeant Ballantine would allege that his talents were merely hired for the occasion, and it is not without pain we see in this, as in many other similar cases, that the profession of the Bar can prostitute zeal, eloquence, and sagacity, to the advocacy of any cause, however wretched or however contemptible; or, as in the present instance, can hold up to public ridicule and contempt a Profession fully as honourable as its own.

SUMMARY OF THE WEEK.

PROFESSOR LAYCOCK ON THE WINDHAM AND TOWNLEY CASES.

In an introductory lecture lately delivered by Dr. Laycock, in the University of Edinburgh, on Medical Psychology and Mental Diseases, the Professor made some passing allusions to the cases of Windham and Townley. In the former instance, Dr. Laycock points out that a due distinction is not drawn between mental diseases and deficiencies, and that the only question originally was, not whether Windham was insane, but whether he was competent or not to manage his large property, and whether it would not have been merciful to protect him from the evil consequences of his youthful defects of judgment. In the case of Townley, Dr. Laycock comments on the discrepancy of the Medical opinions, but inclines to the belief that the man was insane. There was, he observes, an hereditary predisposition to insanity, which was called into activity by a disappointment in love—a circumstance which, in many well-known instances, disturbs the equilibrium of the mental powers, and leads to suicide and homicide, besides a multitude of minor extravagances. Dr. Laycock, in admitting and apologising for the different views taken by Medical men on cases of supposed insanity, adduces, not inaptly, the conflicting opinions held by the British Judges on the case of the ship 'Alexandra,' as showing that law, which is said to be the perfection of reason, is no more fixed in its conclusions than is psychological medicine.

THE BRITISH PHARMACOPŒIA.

It will scarcely be believed that the two following opinions were given by the same Journal on the same book, but such is really the case. The book is the British Pharmacopœia, and the Pharmacopœia Committee, who are extolled in one criticism and decried in the other, are the very same persons :—

Lancet, Jan. 16, 1864.

"This has been the work which the Committee had to carry out, and it has given them almost endless trouble. The wide difference of formulæ in the different national Pharmacopœias, the enormous disparity in strength and composition of preparations of similar name or intended for similar therapeutic uses, constituted a source of innumerable discussions between the various committees. In the end a very close approximation to uniformity has been attained, as is stated by the official writer: not altogether so complete and satisfactory as might be desired, but still enough to warrant the statement above quoted, and more than enough to call for the thanks of the profession to those who have bestowed great toil and distinguished intelligence on the work, and have freely given from their stores of accumulated information all that could be useful for the service of medical practitioners and the public. It will be our duty, in the interests of the profession, to proceed forthwith to the detailed review and criticism of the results they have achieved. It would be unnecessary to say that we shall do so in a spirit of the fullest respect and regard for the great difficulties overcome in the task which they have achieved, were it not that those who have just completed this arduous work might, without some such words of recognition and explanation, feel hurt when any exception is taken to the details of a labour which has undoubtedly been conducted with continued care and unusual ability."

Lancet, May 14, 1864.

"The single practical bit of work is the appointment of a committee to superintend the re-editing of the Pharmacopœia, under the direction of one competent person. We are well satisfied that the opinion we have expressed throughout on this subject is that which the Council has now ultimately adopted; and, leaving the Pharmacopœia Committee to enjoy any such laudations as they can extract from their friends for the part which they have laken in the disgraceful pillage of the profession to the tune of 5000*l.* for a book which any firm of publishers would have had better edited for a tenth of that sum, we may express our satisfaction that the practical revision of the book will now be placed in the hands of one fit person, and that thus an improved result may be anticipated at a comparatively small cost. At any rate we hope to hear no more of the perennial and costly tea-meetings at which the present failure was concocted; and, with a due sense of the responsibility attaching to his work, it is not probable that the new editor will show the foolish desire for secrecy, or the reckless disregard of modern pharmaceutical research, which our commentators and those of the Pharmaceutical Society have shown to characterise the present edition."

DR. MOORE AND THE POOR-LAW BOARD.

Dr. Moore has addressed the following letter to the Poor-law Board. The course he has taken is a most proper one, and the Poor-law Board, by their one-sided conduct, will secure for itself the hearty contempt of the Medical Pro-

fession, who now know what they have to expect from the authorities at Whitehall :—

"To the President and Commissioners of the Poor-law Board.

"Sir, and Gentlemen,—I have the honour to acknowledge the receipt of a communication from you dated the 20th ult., in which you desire to know if I intend to send in my resignation as Medical Officer to the parish of Bethnal Green, as advised by you.

"In answer thereto, I respectfully inform you that my legal advisers being fully satisfied that had the inquiry into the charges been conducted according to the legally-defined rules of evidence adopted in the courts of law or equity, and submitted to an impartial and unprejudiced tribunal, the conclusions arrived at would have been different to those adopted by you.

"It is, therefore, our intention to bring the whole matter before the country in such a form as shall enable us to prove the utter falsity and malignancy of the accusations, the imperfect form adopted in taking the evidence submitted to you, the evident bias of the inspectors, and the injustice of your decision, consequent thereon, and your refusal to re-open the case, so that the whole of the facts might have been brought to your notice.

"As an acquiescence in your recommendation to resign would be a virtual acknowledgment of the justice of your decision, I respectfully beg to inform the Board that I decline acceding to the request.

"I have the honour to remain your obedient servant,
"EDWARD MOORE, M.D., M.R.C.S. Eng.,
"L.R.C.P. Lond., L.S.A.L."

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

We intended in our last number to give the results which had been arrived at by the Medical Council on several very important points connected with Medical Education, but up to the period of our going to press, we had not received the last corrected minutes, and we were unwilling to fill our pages with a multitude of technical details of motions and amendments which terminated in nothing, or to bore our readers with the long-winded discussions of the different speakers, unless they led to some practical end. We regret to state, that although at the end of the week before last it appeared probable that the Council had really come to some definite agreement on certain important principles, that probability was dissipated at the close of the proceedings, when the Council broke up without any definite conclusions at all. We are, therefore, in the position of Tantalus, who finds the water run away from his lips every time that he attempts to imbibe the desired fluid, and we must wait another year, and perhaps several years, before any of the questions now before the Council are settled.

Under these circumstances, it would be manifestly absurd in us to print the enormous mass of material which lies at our disposal, in the form of the official reports of the proceedings, or to report the speeches which we had the opportunity of hearing. We propose, therefore, only to select those portions of the proceedings which we believe may prove of general interest, and to point out the leading features which characterised the general debates. We regret to repeat what we have observed on previous occasions, that the Members of the Council do not, with a few exceptions, appear to be actuated with any desire to promote the general welfare of the Profession, or to uphold its literary or scientific status, but they rather defend, *per fas et nefas*, the interests of their own Colleges or Corporations. From this charge we are bound, in honour and in justice, to except the recent additions to the Council in the persons of Dr. Sharpey, Dr. Parkes, Dr. Quain, and Mr. Rumsey, and perhaps there may be a few more ; but, generally speaking, it is flagrantly apparent that the principle actuating the majority is to take care of number one, in the shape of the body of which each is the representative. Hence, an enormous amount of time is wasted in trifling discussions about technical matters affecting the rights of a particular corporation ; and when any really useful and comprehensive measure is proposed, it is sure to be met by some obstacle arising from its supposed interference with some chartered or corporate right, and every attempt is made to render its provisions abortive by an ingenious system of vexatious opposition. When no other plan seems likely to succeed, that *of speaking against time*, as it is called, is brought into requisition ; and this device was so successful at the last meeting, that many of the Scotch and Irish Members left London before the proceedings were over, and the rest of the Council found a ready excuse for getting rid of the business by pleading the absence of their colleagues.

We have already recorded the debate on Medical Education, which, it will be recollected, was opened by Mr. Syme, followed by an amendment by Dr. Thomson; the upshot being that both the motion and the amendment were lost, Mr. Syme voting *against his own motion!* Truly does the 'Lancet' declare that "Mr. Syme has not shown himself equal to the task he undertook ; he abdicated the command of the discussion, and although commendably brief, what he said was by no means accurate or suggestive ; he destroyed without reconstructing." Our own estimate of Mr. Syme's capabilities as a Medical Legislator we have long ago expressed, and now our opinions are amply justified by the figure cut by Mr. Syme in the recent debate.

It was determined on the 3rd of May, the day after the disposal of Mr. Syme's resolution, that a Select Committee on Education should be appointed, consisting of Dr. Christison, Chairman, Mr. Arnott, Dr. Paget, Dr. Alexander Wood, Dr. Thomson, Dr. Apjohn, Dr. Parkes, and Dr. Stokes, with a view of considering the recommendations of the Council on Professional Education, and the various motions and notices of motion as to Education which had been submitted to the Council. Their duty was to prepare such a report on Medical Education as might be presented, and, if possible, passed during the present session.

With commendable alacrity and zeal, this Committee met and deliberated and prepared the following Report, which we print entire :—

REPORT.

The Committee appointed on 3rd May, relative to Professional Education, have to report, that they have carefully considered all the points referred to them by the Council.

They understand the object of the Council to be, that this Report should comprise a statement of all Recom-

mendations as to Professional Education, arising from the late discussion in Committee of Council, as to which there appears to be a general agreement in the Council, and which may be sent forth this session as Recommendations to the several Licensing Bodies of the Kingdom, or suggestions to them for information. The Committee trust that they have kept this object steadily in view in the following Recommendations:

I.—Registration.

The Committee recommend under this head, that the Regulations proposed in the Report of the Sub-Committee on Registration (Minutes No. 62, pp. 7 and 8) be adopted, with a slight change in No. 3 of these Regulations; which will then stand as follows:

1. That the registration of Medical students be placed under the charge of the Branch Registrars.
2. That each student be only once registered, viz., when he first enrols himself as a Medical student.
3. That each Licensing Body request, from each School of Medicine under its jurisdiction, a list of all students entering on the study of Medicine for the first time at that school, agreeably to a subjoined form.
4. That the Register at each school be closed within fifteen days after the commencement of each session or term.
5. That these lists, as soon as possible thereafter, be transmitted, along with the certificates of each student having passed an Arts examination, to the Branch Registrar of that division of the kingdom where the school is situated, and that he from them frame an accurate Register of Medical students of that division of the kingdom of which he is Registrar.
6. That the Registers of Medical students so prepared by the Registrars, after examination by the several Branch Councils, be transmitted to the Registrar of the General Council, who shall, under direction of the Executive Committee, print the same in alphabetical order, and supply a copy of this authorised list to each of the Bodies in Schedule (A) to the Medical Act.
7. That the several Licensing Bodies be requested, after October 1868, to abstain from examining any candidate for licence or degree whose name does not appear on the authorised list of Medical students.
8. That the Branch Councils be desired to take means to make these regulations known to the Medical students at the various Medical schools.
9. That exceptions allowed by the Licensing Bodies to any of the preceding regulations as to registration, together with the reasons for such exceptions, be transmitted to the Branch Council of the part of the United Kingdom in which they have been granted.

II.—Age for Licence to Practise.

The Committee, after having taken into consideration Mr. Rumsey's notice of motion—that the earliest age for obtaining any licence to practise Medicine or Surgery should be twenty-two, recommend that the Resolution 17 of the Recommendations of Council in 1863, p. 7, be adhered to in the following shape:

1. That the age of twenty-one be the earliest age at which any professional licence shall be obtained; and that the age shall, in all instances, be duly certified.

III.—Professional Study.

The Committee have taken into consideration the notices of motion as to Professional Study, given by Dr. Thomson, Dr. Parkes, and Dr. Storrar, and have come to the following Recommendations, in which not only these gentlemen, but likewise every other member of Committee present, have concurred:

1. That no licence be obtained at an earlier period than after the close of the last winter session of four years of study, after the registration of the candidate as a Medical student.
2. That the course of study required for a licence shall comprehend attendance during not less than four winter sessions, or three winter and two summer sessions, at a recognised Medical school; and that evidence shall be produced that the remaining period of the four years has been passed in the acquisition of Professional knowledge.
3. That, in reference specially to Dr. Parkes' notice of motion, as to duration of sessions, and of courses of lectures, the regulation of the duration of sessions, and the extent and duration of courses of lectures and instruction, be left for the present to the several Licensing Bodies.
4. That it be recommended to the several Licensing Bodies, that the courses of instruction required by them should be framed in such a manner as to secure a due share of attention, both to preparatory branches, and to those more strictly connected with the practice of Medicine and Surgery; and that it be suggested accordingly to these Bodies, that their regulations should be such as to prevent attendance upon lectures from interfering with hospital and clinical study.
5. That, while avoiding for the present all other details, by which this object may be attained, it be recommended, that no subject of lectures be enforced by regulation, to be attended oftener that once.
6. That the Council intimate, that they will view with approbation any encouragement held out by the Licensing Bodies to students to prosecute the study of the Natural Sciences before they engage in studies of a strictly professional character.
7. That the several Licensing Bodies be requested to furnish a short statement of the mode in which their examinations are now conducted, whether by written, oral, or practical examination, and of the length of time a candidate is under examination in each, or all of these ways.

IV.—Examinations.

The Committee have considered the subject of Examinations with peculiar care, which was rendered imperative by the proofs brought before the Council in the late discussion on Education, that the examinations of the Licensing Boards, however conscientiously carried on under the present system, are not always sufficient for their purpose. The subject is one confessedly of much difficulty. The Committee have resolved to recommend:

1. That the Licensing Boards be advised to encourage the periodical examination of students at their several classes.
2. That the final examinations of the Licensing Boards be so carried on as to be an efficient test of the practical acquaintance of candidates with the several branches of medical knowledge, and especially with the practice of Medicine and Surgery.
3. That the Professional Examination for any licence be divided into two parts: the first embracing the primary or fundamental branches of Medicine; and the second the branches directly connected with the Practice of Medicine and Surgery: that the former be not undergone till after the close of the winter session of the second year of professional study; and the latter, or final examination, not till after the close of the winter session of the fourth year of such study.
4. That the examination in Chemistry, Botany, and Natural History may be undergone at an earlier period.
5. That the professional examinations be conducted both in writing and orally; and that they be practical in all branches in which they admit of being made so.
6. That the professional examinations be held by the several Licensing Bodies, except in special cases, at stated periods, to be publicly notified.
7. That Returns from the Licensing Bodies in Schedule (A) be made annually on the 1st of January, and in a subjoined form, to the General Medical Council, stating the number and names of the candidates who have passed their first as well as their second examinations, and the number of those who have been rejected at the first and second examinations respectively; and that the Registrar forward a sufficient number of forms, with a notice for their being returned, in due time.

V.—Supervision of Examinations.

So much has been truly said in the late discussions in the Council, as to the duty which lies with the Council to carry out the enactments of the Medical Act relative to the supervision of the Examinations of the Licensing Boards, that the Committee have felt a great desire to recommend some definite course which the Council might at once pursue for establishing such supervision.

They fear, however, that the Medical Act is defective in this respect, inasmuch as it has not contemplated either the great amount of time and labour required to carry on a really effective supervision of the very numerous Examinations of the Licensing Boards of the Kingdom, some of which do not meet for examination at the seats of the Branch Councils, or the amount of qualifications and professional position necessary to constitute a staff of efficient Visitors of Examinations; and, consequently, has omitted to provide the means of remunerating them for their important services. But, notwithstanding this obstacle, the Committee recommend that a trial of Visitation be immediately made on such a scale as may be a guide to the Council for further regulations on the subject, at a future meeting. For this end they recommend that the Branch Councils be instructed severally to organize a set of Trial Visitations on a scale which may enable them to report upon their success, the conditions for efficiency, and the requisite means for rendering them adequately extensive.

VI.—SUGGESTIONS FOR OBTAINING INFORMATION.

To these Recommendations, which it seems to them advisable that the Council resolve now to adopt, the Committee think it right to add others, as to which the opinions of the Licensing Bodies, and of the Medical Schools connected with them, should be requested in time for the consideration of the Council at its next Session, viz.:

1. Whether, in the opinion of the Licensing Bodies, the commencement of professional study, by which the duration of it must be regulated, should be held to be only entrance on such study at a recognised Medical School?

2. Whether a "Medical School" may be better or otherwise defined than as one where there is an opportunity of studying at a General Hospital, containing at least 80 beds for patients, and also a Teacher of Practical Anatomy recognised by a Licensing Body?

3. Whether entrance on apprenticeship should be held as another way of constituting the commencement of professional study?

4. Whether the same privilege be extended to pupilage under a registered practitioner, who has charge of a union workhouse, a dispensary, or an hospital, though destitute of Medical or Surgical teachers?

5. Whether any other mode of study may be similarly recognised as the commencement of professional study?

6. Whether, looking to the great extension of the primary or fundamental Sciences of Medicine during the last forty years, the subjects embraced in courses of lectures on these sciences may not be better arranged and treated than now; so that they may be made more applicable than they are at present to the practical instruction of Medical students, as distinguished from general students?

7. Whether it be advisable or not, and if advisable, whether, and how, it may be practicable to adopt, in part at least, the principle of *ad eundem* examinations; so that a candidate, who has been satisfactorily examined, in part or completely, for any professional title conveying the right of practice, shall not be subject to re-examination on precisely the same branches by another Examining Body, before whom he may appear as candidate for the same, or a different, qualifying professional title?

8. Whether it be advisable and practicable, for the relief of candidates for licences from superfluous examinations, to establish in England, Scotland, and Ireland severally, a conjunct examining board, before whom candidates may be subjected to a single series of examinations for the "double qualification" of physician and surgeon?

9. Whether it be desirable that the oral and practical parts of the professional examinations should be so conducted as to be open to registered Medical practitioners and registered Medical students?

Lastly,—In conformity with the notices of motions by Dr. Acland, the Committee recommend the Council to appoint a Select Committee, to consider and report at the next session of the Council, what are the subjects of examination which should be required of all students prior to commencing the prescribed course of professional education, and what are the professional subjects of examination which should be required of all candidates before they receive the license to practise medicine or surgery, or medicine and surgery.

R. CHRISTISON, *Chairman.*

This was the admirable Report which we hoped to be able to present to our readers last week, with the gratifying addition that it had received the sanction of the Medical Council; but no—the cup of satisfaction it presented to our lips only to be dashed down again; and we find that instead of at once receiving and acting on this Report, the Medical Council began to discuss it all over again, clause by clause, until, as we have before intimated, the patience of several of the Members of the Council was worn out: and although some of the clauses were passed, the whole subject was postponed for another year. The suggestions contained in the Report, however, are so valuable and are so much marked by good sense and moderation, that we make no apology for presenting them to our readers, to whose careful perusal we cordially recommend them. Many, if not most, of the recommendations, we may observe, are or have long been adopted by some of the chief Examining Boards in England.

Towards the close of the proceedings on Saturday, May 7, the following resolution settled the Education question for the present session:—

18. Moved by Dr. Acland; seconded by Dr. Andrew Wood; and agreed to: "That the report of the Select Committee on Education be forwarded to the various bodies in schedule (A), with a letter from the registrar, to the effect that the report is under the consideration of the Council, and calling their attention to the suggestions of the report, and soliciting their observations thereon; also, distinguishing the resolutions which have been adopted by the Council from those which have not yet been considered; and that it be referred to the Executive Committee to carry this resolution into effect."

PRIVILEGES OF THE MEMBERS OF THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The following discussion will be read with some interest, although the point at issue is left undecided:—

Friday, May 6th.—The Registrar read a correspondence which had taken place between the Poor-law Board, the Guilteross Union, the Faculty of Physicians and Surgeons of Glasgow, and the Registrar of the General Medical Council, in reference to the question whether the licence of the Faculty of Glasgow confers a qualification both in medicine and surgery.

Dr. Fleming said there was no question before the Council. The Poor-law Board had merely requested Dr. Hawkins, the Registrar, to give his opinion on the subject, twhich he had done in a very accurate manner, to the effect hat the Council had come to no positive decision with regard to the powers of different boards to grant qualifications. The Poor-law Board did not understand the position of the Medical Council. The Faculty of Physicians and Surgeons of Glasgow had been asked if they had a right to grant the degree of M.D. All that they contended for was that they were entitled to grant a diploma which conferred, in Scotland, the power to practise medicine and surgery. The Council had not been asked for their opinion; and he conceived the question lay between the Faculty of Physicians and Surgeons of Glasgow and the Poor-law Board, or for a court of law to determine.

Mr. Syme said that at an early period of their meetings the Poor-law Board applied for information as to the import of

the titles conferred, and the Medical Council had declined to express any opinion on a matter which was more suitable for a court of law. The Faculty of Physicians and Surgeons of Glasgow had always required a complete education and instituted a complete examination.

Mr. Alexander Wood said the question was of much more importance than would at first sight appear. It was a question as to the construction of the 31st clause of the Medical Act—"That every person registered under this Act shall be entitled, according to his qualification or qualifications, to practise medicine or surgery, or medicine and surgery, as the case may be." The law had drawn a distinction, and the Poor-law Board had determined to employ no man who had not a qualification to practise both medicine and surgery; and with every respect for the Faculty of Glasgow, the law did not, in his opinion, give them the power to practise medicine, but only the power to practise surgery. Their charter did not contain a word about physic or medicine; and therefore, while the law remained in its present state, he conceived the Medical Council had no power to give to the Faculty of Glasgow a power which their own charter did not bestow. With regard to Dr. Fleming's motion, he thought it was scarcely civil to a public Board, asking for information, to say they were satisfied with the answers already given. He thought they ought to refer the Poor-law Board to the charter of the Glasgow Faculty, and say it is a legal question which it is not competent for the Council to answer.

Mr. Arnott said the Glasgow Faculty stood in the same position as the College of Surgeons in Dublin and Edinburgh, having a right to grant a qualification in surgery only. He did not pretend to know the legal bearing of the question.

Some discussion took place as to the form in which the resolution should be worded, and, eventually, the following was agreed to:—"That in reply to the inquiry made by the Secretary of the Poor-law Board, in regard to the powers conferred by the licence of the Faculty of Physicians and Surgeons of Glasgow, the registrar be instructed to intimate that the question involving the legal interpretation of a charter is one which the Council is not competent to answer."

GENERAL CORRESPONDENCE.

BLEEDING FROM THE UMBILICUS.

To the Editor of the Medical Circular.

SIR,—Should you think the following an interesting case, its insertion will oblige

Yours, &c., A STUDENT.

Sarah L., aged five, fair, of rather a strumous type, but nevertheless healthy, and has never had any manifestation of scrofula. From the time of her birth till now, at intervals varying from a day to a week, she has been subject to bleeding from the umbilicus, sometimes more than once a-day; at times very slight, at other times profuse enough to stain through all her underclothes.

There has been no hæmorrhage from other parts of the body except from the gums, but this is very slight, and is evidently owing to decayed teeth. Upon pulling apart the folds of skin at the umbilicus there is seen a small raw surface, from which, the mother states, the blood exudes.

I have never, myself, seen her during the bleeding, which is generally brought on by her making some exertion. Tannic acid and glycerine are being applied to the raw surface, and tincture of sesquichloride of iron given internally.

THE GOVERNMENT SHOULD CONFER DEGREES.

To the Editor of the Medical Circular.

SIR,—It is a grave question, yet, nevertheless, a perfect truth, that all our medical and surgical institutions (near upon twenty in number) of this country are wholly and solely supported (with but few exceptions, if any) by the sale of diplomas and certificates, under monopolizing laws and bye-laws; therefore it follows, as a matter of course, and to a positive certainty, it must sooner or later come to pass, that all our institutions of this country must, from imperative necessity, sell their credentials, in order to keep their institutions going and the wolf from their doors. Good gracious! how, for instance, are such institutions to obtain the means (except by the sale of their qualifications) of paying lawyers, examiners, librarians, clerks, secretaries, museums, curators, beadles, macebearers, hall and college porters, rents, taxes, stamp duties, postages, stationers, with a host of other incidental charges of which I have not the least conception whatever? These parties must, one and all, be paid for their services, and are perpetual drains upon the Licensing Bodies of this country. How need we wonder at the admission (so often reiterated and censured by the 'Lancet,' so recently as last month) into the Profession of subordinates, wth its *ad eundem gradum* regulations, including midwifery and dentists' certificates. The only poser for this state of things would be for the Government to appoint boards of examiners, and who should be paid by the State itself, and thus give to each examiner a fixed fee for his services. This I conceive to be the regular poser for such glaring abuses, which still remain a blot and an opprobrium to our healing art. And then—last, but not least—when gold speaks, all other speeches are in vain.

I am, Sir, &c., A CONSTANT READER.

Herts, May 6th, 1864.

TREATMENT OF UTERINE HÆMORRHAGE.

To the Editor of the Medical Circular.

SIR,—Having read the "Original Communication" of your correspondent on "Uterine Hæmorrhages" in your number of May 4, I beg most respectfully to state that the "*new method*" adopted by him, is one *invented* and *adopted* by me, now upwards of *twenty-five years since*, having read a paper before the Medical Section of the British Association, held at Newcastle-on-Tyne, and of which honourable mention is made in their 'Transactions,' more especially its applicability to Placenta Prævia. Honourable mention is recorded of the several inventions in the 'Medical Directory,' page 593. The instrument was made for me, also my "Elastic Pessaries," by the Messrs. Brown and Son, surgical instrument makers. I am, &c., THOS. R. TORBOCH, M.D.

Darlington, May 4, 1864.

Births, Marriages, and Deaths.

BIRTH.

HORGAN.—On the 11th inst., at 32 Lower Pembroke street, Dublin, the wife of William Cronin Horgan, Esq., M.D., Coroner of Drogheda, of a daughter.

MARRIAGE.

HUNT—HALL.—On the 10th inst., at St. Mary Abbotts, Kensington, by the Rev. Henry Geary, M.A., incumbent of Christ Church, Herne Bay, Thomas Hunt, Esq., F.R.C.S., 23 Alfred place, Bedford square, to Caroline, second daughter of the late Benjamin Hall, Esq., of Shepherd's bush.

DEATHS.

COCKE.—On the 9th inst., at The Elms, Chapel, Essex, Thoma Golding Cocke, Esq., surgeon, aged 57.

DRYSDALE.—On the 9th inst., at Liverpool, Mary Mortimer, wife of J. Drysdale, Esq., M.D., aged 38.

HOWELL.—On the 8th inst., Mr. Thomas Howell, surgeon, New Kent road, aged 49.

ROYAL INSTITUTION OF GREAT BRITAIN.—A general monthly meeting was held on Monday, May 9, 1864; William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair. The Hon. Henry Frederick Cowper, George Clive, Esq., M.P., Lieut.-Col. George Palmer Evelyn, William Dell, Esq., and William Graham, Esq., were elected members of the Royal Institution.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 3rd inst., and when eligible will be admitted to the pass examination:—Frederick Barton, University College; F. H. Burdett, Birmingham; W. H. Carruthers, Manchester; F. T. Coates, University College; Thos. Cole, St. Bartholomew's; George Crowe, University College; Thomas Cuddeford, St. Bartholomew's; H. D. Dod, St. Bartholomew's; Joseph Fall, St. Bartholomew's; J. W. G. Farwell, St. George's; J. C. Galton, St. Bartholomew's; J. D'A. Harvey, University College; W. B. Holderness, St. George's; J. P. Hughes, University College; Robert Hullah, St. Thomas's; T. M. Joseph, University College; P. Q. Karkeek, St. Bartholomew's; William Keen, St. George's; Josiah Leale, University College; Joseph M'Williams, Manchester; G. S. Madeley, Manchester; J. M. Moore, Edinburgh; William Nuttall, Manchester; J. I. Ransford, St. George's; C. L. Ridant, St. George's; A. M. Roberts, University College; G. C. Sanders, St. George's; Robert Sephton, Manchester; T. T. Taylor, St. Mary's; H. A. R. Thomson, St. George's; Frederick Turner, Sheffield; Joseph Westmorland, Leeds; S. H. Woodgates, Westminster.

The following gentlemen passed their primary examinations on the 4th inst.:—Robert Aldren, Edinburgh; Robert Barker, Newcastle; George Birch, Guy's; T. H. Brocklehurst, Manchester; J. H. Croft, Guy's; G. H. Dodsworth, St. George's; G. H. P. Evans, St. Bartholomew's; A. E. Fluder, Guy's; H. E. Forward, Birmingham; A. B. Fry, Guy's; G. F. Fulcher, Edinburgh; T. S. Gell, Edinburgh; J. M. Gordon, Edinburgh; J. K. Hyland, Dublin; Joseph Kirk, Manchester; A. J. Leggatt, St. George's; C. F. Lethbridge, University College; Francis Lett, Guy's; A. A. M'Clure, New York; G. J. Muriel, Guy's; C. E. Proctor, St. Bartholomew's; D. W. Robertson, Edinburgh; W. B. Rule, St. George's; W. O. Withers, King's College; Horatio Wood, Birmingham.

The following gentlemen passed their primary examinations on the 5th inst.:—F. L. Attwood, St. Mary's; M. H. Cantrell, University College; Vaughan Carnley, Hull; E. L. De Morgan, University College; J. R. Dunn, Middlesex; R. W. Goldie, Edinburgh; T. G. P. Hallett, University College; J. T. Hughes, Aberdeen; G. A. Kenyon, St. George's; Osmer King, Guy's; F. B. Lardner, Guy's; Augustin Le Rossignol, London; J. M. Macfarlane, Edinburgh; W. H. Plaister, Bristol; James Taylor, Glasgow; David Thomas, Edinburgh; W. K. Treves, St. Thomas's; Polyxen Vaudagne, University College; A. C. Wakefield, Edinburgh; A. M. Watson, Edinburgh; E. F. Willoughby, University College.

THE FELLOWSHIP.—The following gentlemen have just passed the preliminary examination in Classics, Mathematics, and French, for the Fellowship of the London College of Surgeons:—George William Smith, Aytoun street, Manchester—diploma of membership dated Jan. 26, 1855; Samuel Edwin Solly, Savile Row, a student of St. Thomas's Hospital; John Sebastian Wilkinson, Davies street—diploma of membership dated May 15, 1857.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on the 5th inst.:—Thomas Henry Knott, Guy's Hospital. As an Assistant:—John Evans, Cardiff. The following gentleman also on the same day passed his first examination:—James Taylor, Anderson's University.

UNIVERSITY COLLEGE, LONDON.—The presentation of prizes to the students of the Faculty of Medicine who stood the best in the class examinations at the close of the Winter Term took place on Monday week, in the Botanical Theatre of the College. Lord Wodehouse presided.

THE UNIVERSITY OF LONDON.—On Wednesday a meeting of the Senate and Fellows of the University of London was held at Burlington House, for the purpose of presenting to the Chancellor, Earl Granville, the candidates admitted as graduates and undergraduates during the present academical year. Earl Granville occupied the chair.

KING'S COLLEGE, LONDON.—The annual distribution of prizes to the students in the department of the evening classes took place at King's College on Friday, in presence of a large assemblage of persons, a considerable number of whom were ladies.

ROYAL MEDICAL BENEVOLENT COLLEGE.—The annual festival of this charity was held on Saturday night at Willis's Rooms; Sir Charles Locock, M.D., in the chair. About two hundred gentlemen sat down to dinner, and among those present were:—Sir John Fisher; the Master of the Temple; Mr. C. G. Dupré, M.P.; Mr. G. Lyall, M.P.; Mr. Wm. Angerstein, M.P.; Colonel Walker, Colonel Palmer, the Rev. Dr. Thornton, the Rev. Dr. Mortimer, Dr. Seaton, the Rev. C. Mackenzie, Mr. Stillwell, Dr. Babington, Dr. Billing, Dr. Randall, Dr. Chowne, Mr. Fergusson, Dr. Ray, Dr. Aldis, Dr. Sieveking, Mr. Prescott Hewett, Mr. Erichsen, &c. Donations to the amount of upwards of 1,100*l.* were announced in the course of the evening. The report of the council for the past year stated that a sum of 6,130*l.* had been received from bequests to the college, and that, notwithstanding the whole of the money so received had been invested, instead of being carried, as in former years, to the current receipts, the balance of ordinary liabilities has been reduced by 800*l.*, while the amount of stock belonging to the Endowment Fund has advanced from 3,700*l.* to upwards of 10,000*l.* Sir C. Locock, in proposing "The Health of the President, Lord Chelmsford, and Success to the Royal Medical Benevolent College," referred to the rapid growth of the institution as an evidence of the noble and generous support which had already been given to it on the part of the Medical Profession and the public. He referred to the fact that the number of applications for admission was greater than the vacancies, regretted that such was the fact, and hoped that the time would shortly arrive when the accommodation provided would be equal to all the demands upon it. "The Health of the Chairman" was subsequently proposed by Mr. Dupré, M.P., and similar honour was done to the treasurer and other officers of the charity.

UNIVERSITY OF CAMBRIDGE.—The examinations for medical and surgical degrees will commence on Monday, the 30th of May, at 9 a.m., in the Arts' Schools. Candidates for the degree of M.B., intending to offer themselves for examination, are required to signify the same to the Regius Professor of Physic.

CORONERS' INQUESTS IN CENTRAL MIDDLESEX.—Dr. Lankester, coroner for Central Middlesex, has just published as an address to the National Association for the Promotion of Social Science, his first annual report on the subject of coroners' inquests, held from August 1st, 1862, to July 31st, 1863. The report contains an analysis in which Dr. Lankester states he has been assisted by Dr. Wm. Hardwicke, his deputy, in the various cases in that period, and is replete with information of a most useful and interesting character. The coroner states that the population of the Central District is 805,955, while the inquests during the period specified have been 1,080, or one inquest for every 746 persons in the population. The population of the same district in 1851 was 681,603, and the average number of inquests held annually by his predecessor, Mr. Wakley, from 1857 to 1861, was 879, or one inquest to every 735 of the population, showing that the number of inquests in proportion to population had diminished during the first year the present coroner had held the office. The largest number of inquests had been held in St. Pancras—viz., 317, in Marylebone 229, and Islington 132, 128 in Paddington, 57 being at St. Mary's Hospital. Of the 1,080 cases, 567 had been proved to be from natural causes, 346 accidental deaths, 70 suicides, 68 coming within the category of homicide, infanticide, and manslaughter, and 29 from unknown causes. The coroner complains of the inadequacy of the registration system, and observes "that the registration of death and the burial of the body is of very common occurrence in London. He refers to a statement made by Dr. Buchanan, medical officer of St. Giles's,

that 45 deaths were registered in St. Giles's in 1862, and the corpse in each case interred, about which there ought to have been an inquiry." He cites several cases as an example, and adds, "Not only are unsatisfactory certificates given, but medical certificates are registered in which medical men have not seen the person alive; and in some cases, where they have neither seen them alive nor dead." It had come also to his knowledge that the registration had taken place in cases of violent death and sudden death without any appeal to the coroner of the district, and he properly remarks, "It is very evident that such a system is fraught with danger to the public, and that it ought not to be left to the judgment of the registrar as to whether the coroner shall be informed of the entire absence or irregularity of a medical certificate." The desirability of the attention of Government to this subject is enforced. Some interesting details are given in reference to the increase of the crime of infanticide, from which the deduction is made that such crime is six times more frequent in Paddington and St. Giles's than in Islington, is twice as prevalent in Hampstead as in St. Marylebone, and twice as great in St. Pancras as in Islington. In reference to season of the year, the fewest number were held in August, and the largest in December, the accidents by fire contributing largely to the increase in the winter months. After treating upon the deaths from natural causes, and showing the value of the functions of the coroner's court in relation to these diseases, many being contagious and arising from circumstances over which man has most distinct control, and by inquiry the progress of pestilence being not unfrequently stayed, the coroner enters into the statistics of suicide which came under his notice, and concludes his very able report by demonstrating the vast importance of the inquiries of the coroner's court in relation to the safety of life in the only country in Europe in which the Court exists in all its integrity.

MISS GARRETT AND THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.—We understand that the College of Physicians have taken the opinions of the Attorney-General and Mr. Cleasby as to the legal question of admitting Miss Garrett to examination, and that, acting on their advice, the College has determined to decline receiving Miss Garrett's application.

UNIVERSITY OF ST. ANDREWS.—List of candidates who obtained the degree of M.D. on April 29, 1864:—Wm. Sankey, M.R.C.S.E., L.S.A., Sutton Valence, Kent; Wm. Parker, L.F.P.S., L.S.A., Bermondsey; Jas. Walsh, M.R.C.S.E., M.R.C.P.E., L.M.I., Staff-Surgeon, Limerick; John Alfred Lush, M.R.C.S.E., L.S.A., Salisbury; John Fenton, L.R.C.P.E., F.R.C.S., L.S.A., Liverpool; W. P. Charsley, M.R.C.S.L., Principal Civil Medical Officer, Ceylon; Wm. Nassau Irwin, L.R.C.S.I., L.R.C.P.L., D.M., Monaghan; Walter McD. Kelly, L.R.C.S.Edin., L.S.A., Crook, Durham; Thomas Wilson, M.R.C.S.E., L.S.A., Hull; J. Sydney Smith, M.R.C.S.E., L.M., L.S.A., Tiverton.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAY 18.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Hunterian Society, 8 p.m.—Mr. P. Y. Gowlland, "On Cases of Obstinate Constipation relieved by Division of the Sphincter."

THURSDAY, MAY 19.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; Great Northern Hospital, King's cross, 2 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopœdic Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Hullah "On Music (1600—1750);" Chemical Society, 8 p.m.—Dr. Gladstone, "On Chlorophosphide of Nitrogen."—Mr. Dancer, "On the Constitution of Wood Spirit."—Drs. Williamson and Russell, "On an Apparatus for Gas Analysis."—Dr. Williamson, "On Atomic Weights of Metals;" Harveian Society, 8 p.m.—Discussion "On Carbuncle and Boil."

FRIDAY, MAY 20.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal Institution, 8 p.m.—Mr. J. Nasmyth, "On Day and Night in the Moon."

SATURDAY, MAY 21.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Alexander Herschel, "On Falling Stars."

MONDAY, MAY 23.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAY 24.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOK RECEIVED FOR REVIEW.

Stimulants and Narcotics: their Mutual Relations. By Francis E. Austie, M.D., M.R.C.P., &c. London: Macmillan and Co., 16 Bedford street, Covent garden.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

IN consequence of the proof-sheets of our article on the British Pharmacopœia not having arrived in time, we are compelled to postpone its publication until next week.

QUESO.—In paralysis death from congestive pneumonia is not infrequent. In partial paralysis at the function of the healthy and diseased parts the sensibility is most requisite, owing to the fact that, while compression of the bone by means of the depressed bone exists in one part and occasions want of motion and feeling, another part of the cord or a nerve running from it is not compressed but irritated, and, as always obtains, the pain is referred, not to the part directly acted upon, but to the extremity of the nerve or nerves communicating with that part. Fractures in the lumbar region running into the sacral will be attended with paralysis from the knee down; occurring, however, in the dorsal, the paralysis will involve the entire of the lower extremity.

HOMO SUM.—The subject is still under the consideration of the Government, and Sir George Grey has prepared a Bill the provisions of which will meet some of the evils in question.

YOUNG STUDENT.—In inflammation red corpuscles are first increased and then diminished; the white corpuscles are not really increased, but merely seem so from the relative diminution of the red. The adhesiveness of the white is produced by the inspissation of the blood plasma. The increase of fibrin in the blood arises from the waste and oxidation of tissues. The hæmorrhage of inflammation is never a mere transudation; it proceeds from rupture of the bloodvessels, or from breaking down of the hematine or blood-colouring matter. Solid œdema results from direct effusion of fibrin or of the liquor sanguinis, of which the more watery parts are removed, leaving, however, the comparatively solid fibrin. It is quite possible that there may be a direct *secretion* of the fibrin.

MR. L. will find that we have alluded to the subject this week.

MR. A. MUIR.—The list has been received.

INQUIRER.—Fracture in the *young* is more frequently *transverse*, while in the aged it is usually more or less oblique. Compound fractures unite by the granulation of bones; these granulations pour out plastic material, which is speedily, if all things be favourable for its development, converted into bone. Many think that there is an exfoliation of that part of the bone which lies in the pus, and that after the exfoliation has been accomplished the granulations are formed.

THE PHARMACEUTICAL SOCIETY.—The card has been received.

MR. L. B.—The circumstances are not explained with sufficient distinctness to enable us to form an opinion.

DR. J. L. E., BIRMINGHAM.—The *Laminaria Digitata* may be procured of Mr. C. W. Krohne, 241 Whitechapel road, London.

A FELLOW.—It will be seen by reference to our report of the meeting that the point has not yet been decided.

TOXICON.—The active principle of the *Lobelia Inflata* has not been definitely determined, so far as we are aware. The physiological properties of the plant are those of a sedative.

PRACTITIONER.—An excellent sedative liniment which would be adapted to your case is:

Tinct. opii., ʒj.;
Chloroformi, ʒij.;
Liniment. saponis, ℥ij. Ms. ft. liniment.

Let this be rubbed in night and morning, or even three or four times daily, till its beneficial effects are experiencd.

HARRIS *v.* TWISS.

We have received the following statement, which we publish with no other comment than to recommend Dr. Harris's case to the favourable notice of the Profession :—

SIR,—We beg to call your attention to a brief *résumé* of the above case, which has occupied a large share of the attention, not only of the Profession, but of the public.

The plaintiff in this case was Doctor Pitt Harris, Medical Officer of the Newport Dispensary, Nenagh Union, a gentleman who accepted the appointment with the knowledge that more than one of his predecessors had been driven from Newport by the most determined persecution; and one of his predecessors lately asserted publicly, in the Petty Sessions Court, that "he never would have resigned the appointments but for the persecution which he suffered from Mr. Twiss (the defendant).

For the last eighteen months, Mr. Twiss, a Poor-law Guardian, and a member of the Committee of Management of the Newport Dispensary, possessing property to the amount of between three and four thousand a year, put in force all those means of annoying Dr. Harris with the existence of which every Medical officer must be well acquainted, but finding that nothing could disturb the equanimity of the doctor, and that he showed a quiet determination not to be driven out of Newport as his predecessors had been, Mr. Twiss at length proceeded to open slander, and at a public meeting of the Board of Guardians, held in Nenagh, where he knew that reporters from every newspaper in the county attended, accused the Medical officer of incapacity and neglect, in "failing to discover that the bones of a boy's arm were broken, and refusing to set them, and that the father of the boy (his own bailiff) had to send for a bone setter, who set the bones."

The position and capacity of this bone setter may be imagined from his own evidence at a subsequent investigation before the Committee of Management. He said that "he was a bone setter since *before* he was born, and his generation before him."

Dr. Harris immediately directed his solicitor to take proceedings against Mr. Twiss for oral slander, and accordingly he was served with a writ, damages laid at 1,000*l*. Mr. Twiss filed three pleas in defence, viz. :—1st, a denial of the words; 2nd, a denial of the words in the defamatory sense attributed to them; and 3rd, *privilege*.

The plaintiff was advised by counsel, that he would get a verdict on the first two pleas, but would be defeated on the plea of privilege, and, nevertheless, resolved to go to a jury, hoping that, should a jury endorse this opinion as law, it might possibly lead to a revision of a law which is a violation of all justice, a law which gives a guardian the "privilege" of blasting the professional reputation of a Medical man without fear of punishment. The Judge (as was predicted by the plaintiff's counsel) directed the jury to find a verdict for the plaintiff on the first two pleas, and for the defendant on the third, "privilege," with costs. Taking into consideration these facts, and that, in reality, the plaintiff, Dr. Harris, fearlessly fought the battle of the Profession against wealth and power, a committee has been formed of professional and non-professional gentlemen, with the object of calling on his brother practitioners not alone to indemnify him, but by doing so to protest publicly against a state of the law under which each in his turn may suffer.

Subscriptions will be received by the following gentlemen: —George W. Bassett, proprietor of the 'Southern Chronicle,' Limerick, and Thomas Glover, Francis street, Limerick, Hon. Secs.; Edward Hamilton, M.D., F.R.C.S.I., Surgeon of Stevens' Hospital, 123 Stephen's green, West, Treasurer for Ireland; George Woods, M.D., Surgeon of the General Hospital, Southport, Treasurer for England.

Royal College of Physicians of LONDON.

FIRST Part of the PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination of Students who have completed their Second Winter Session of Study at a recognised Medical School will commence on Tuesday, June 7th.

SECOND PART of the PROFESSIONAL EXAMINATION.—An Examination of Gentlemen who are eligible for admission to the Second Examination for the Licence will commence on Tuesday, June 14th.

Graduates in Medicine of a University recognised by the College, Licentiates of the Royal College of Physicians of Edinburgh, or of the King and Queen's College of Physicians in Ireland, and Registered Medical Practitioners qualified before January, 1864, are admitted to Examination, under special Bye-laws.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

H. A. PITMAN, M.D., Registrar, Pallmall East.

ARMY MEDICAL DEPARTMENT,
7th May, 1864.

A Competitive Examination for

ASSISTANT SURGEONS in her Majesty's Army will commence on Monday, the 8th August, at Ten o'clock.

Candidates up to 30 YEARS OF AGE are eligible to attend.

Application should be made in writing to the Director-General of the Army Medical Department, 6 Whitehall yard, for the printed form, which is required to be filled up before any name can be placed on the list.

J. B. GIBSON, Director-General.

Society for Relief of Widows and

ORPHANS OF MEDICAL MEN.—INSTITUTED 1788.—Incorporated by Royal Charter, 1864.—The 76th ANNIVERSARY DINNER of this Society will take place on Saturday, May 28th, at the Albion Tavern, Aldersgate street.

STEWARDS.

THOMAS ARTHUR STONE, Esq. (President and Trustee), in the Chair.

John Adams, Esq.	Charles Hawkins, Esq. (Trustee).
W. H. Baillie, Esq. (Hon. Member).	H. S. Illingworth, Esq.
Henry Blenkarne, Esq.	Henry Jeaffreson, M.D.
E. A. Brande, Esq., V.P.	W. Laurence, Esq., F.R.S.
I. Baker Browne, Esq.	James Middleton, Esq.
William Carr, Esq.	Charles Miles, Esq.
Charles Collambell, Esq.	John Morgan, Esq.
George Critchett, Esq.	James Nichols, M.D.
T. B. Curling, Esq.	G. Hamilton Roe, M.D. (Acting Treasurer).
Thomas M. Daldy, M.D.	
William Dickenson.	Henry Sterry, Esq.
John Gregory Forbes, Esq.	Rev. Arthur Stone.
Henry William Fuller, M.D.	Edward Tegart, jun., Esq.

Tickets One Guinea each, to be obtained from the Stewards, from the Secretary, or at the Tavern.—Dinner to be on table at half-past six o'clock precisely.

Any Registered Member of the Medical Profession residing in the County of Middlesex, or within the limits of the London District Post, is eligible as a Member of the Society, at a subscription of Two Guineas a year. Widows and Orphans of Members of not less than two years' standing are eligible for relief, and to such applicants relief was granted last year to about £2,000.

S. W. J. MERRIMAN, M.D.,
53 Berners street, W. Secretary.

Anatomy, Physiology, Pathology,

and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland Place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

The Medical Baths and Fumigations.

40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Baréges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic sease where internal medicines are inadmissible, or have altogether failed effect. Imitations having arisen, be particular in the address.

Brass and Zinc Door-Plates.

—C. BARR continues to supply Name-Plates for Office and Surgery Doors, engraved in the best manner and at moderate charges. Chemists' Shops fitted up with Window-sill Plates in the plain or O.G. patterns. Lists of Prices post free.

Plates altered and repaired.—Country orders punctually attended to.

36 CHANDOS STREET, CHARING CROSS, W.C.

Medical Fixture and Glass Ware-

HOUSE.—W. HAY and SONS, 25 Little Queen street, Lincoln's inn fields, beg to inform the Profession that they Fit-up every description of Medical Shops and Surgeries, and have in Stock a large assortment of New and Second-hand Drawers, Counters, Desks, Dispensing Screens, Bottles, Jars, and every requisite for the above.—A large Assortment of Medical Lamps.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 312.)

Prec. 17.—There is one precaution which ought to have been mentioned the very first of all, but I forgot to do so. When a medical man is summoned to attend a case of labour, he should go as soon as possible. It is very important to be present at the birth, that we may be enabled to use various precautions suitable to the case. I have seen three or four cases of severe hæmorrhage after delivery, occurring before my arrival, which, from the facility I had in each instance in arresting the loss of blood, I believe I could have entirely prevented, had I been present at the birth. One of these cases I shall relate in greater detail in a subsequent communication. I will give the chief facts of the case briefly now:—The patient had been confined half an hour or more before my arrival. She was perfectly blanched, and on my asking her how she felt, she said she could not see. The uterus was as large as if there were still another child. There was only an ounce and a half of brandy in the house, and while the nurse poured that, neat, down her throat, I passed my hand into the uterus, and found that the placenta was only partially detached. The rest of the cavity of the uterus was filled with clots. On removing them and the placenta, the uterus immediately contracted firmly, and nothing more was required to be done. In this case the hæmorrhage was set up by the placenta being only partially separated. If the uterus had been followed down as the child was being born, and then afterwards commanded by the hand, it is most probable that the placenta would have become entirely detached in ten or fifteen minutes, so as to have enabled it to be removed by traction, and no hæmorrhage would have occurred.

The Remedies.

Before I proceed to consider the remedies which have been found useful in the treatment of post-partum hæmorrhage, I may state that I object most strongly to the present routine method of treating the complication. In obstetric works, we find a page or two given to the causes of flooding after labour, and two or three pages to its treatment. Although the causes are numerous, and various in their nature, the treatment is the same in all cases. We are advised to try a number of remedies one after another until we succeed in arresting the hæmorrhage, beginning with mild, and ending up, "as a last resource," with severe measures, without the slightest reference as to the cause or causes which have set up the hæmorrhage, or keep it going. Can anything be more unscientific or unsatisfactory than such a plan of treatment? To those whose only object is to stop the hæmorrhage, the routine method will be quite satisfactory. By trying one remedy after another we can generally manage to stop the hæmorrhage; but we ought not to be content with merely stopping the discharge: we should endeavour to arrest it quickly, and preserve as much of the blood flowing in the patient's body as we can. A pint of blood saved, and a pint of blood lost to the patient may make all the difference between a rapid and a tedious convalescence—may make all the difference between a successful and a fatal issue. The only way of arresting flooding quickly is by removing the cause or causes which keep it up. What would be the answer of a practical medical man if he were asked how he would treat a certain case of menorrhagia or metrorrhagia? "It would depend upon the cause or causes;" and that would be the answer I should give to any one who asked me how I would treat a case of post-partum hæmorrhage. The further discussion of this topic I shall leave until I come to consider the causes, their diagnosis, and treatment, and will now go on to describe the numerous remedies which have been found useful in the treatment of flooding after delivery. We should learn all of them thoroughly, for although, in some cases, by employing a right treatment, we may only require a single remedy; in other cases, such as in obstinate inertia, or where the causes are many in number, it may be necessary to use the majority of them.

Pressure on the Uterus.—There is nothing equal to the hand for compressing the uterus. We may find means with which we can apply the pressure with more force; but the hand alone can give us, at the same time, information as to the state of the uterus—as to whether it be getting larger or smaller; as to whether it be still flabby or now contracted; as to whether it be tender or not—all of them points of great importance. If one hand only is necessary, the left will be the most convenient; we want the right to lift the clothes up slightly, to enable us to see the amount of discharge coming away or to apply other remedies with. In some cases, pressure with both hands, from their grasping the uterus more completely, acts beneficially in stimulating the uterus to contract in a regular manner. Whether one or two hands be used, we should grasp as large a portion of the uterus as we can, and apply equal pressure. Kneading the uterus with the tips of the fingers is very useful in obstinate instances of inertia, where there is great difficulty in setting up contraction; but in ordinary cases I prefer the application of equal pressure over as large a surface of the uterus as one or two hands can command, as it produces a more regular contraction.

Cold.—I shall first consider the various ways of applying cold to the uterus externally. They are generally more effectual when combined with pressure. Pressure with a pair of cold hands will, in some cases, suffice to excite a firm contraction of the uterus. Another plan, which sometimes answers, is to place a number of small plates, one at a time, over the fundus of the uterus; as one plate gets warm, replace it by another. These two methods have the advantage of not wetting the patient, which cannot be avoided when cold water is used. The plan I usually adopt is to have a bucket of cold spring-water placed in a chair close to my side. I begin by placing both my hands in the water, and keeping them in until they feel very cold. I then take out one (say the left), and place it immediately on the bare abdomen, over the fundus of the uterus; the other remains in the water. When the left hand begins to regain its warmth it is removed and placed in the cold water again, and the right hand takes its place; and so on *vice versâ*. I have found this plan often effectual; it keeps up a continual application of cold, without wetting the patient much. Cold may be applied to the uterus with advantage by means of a large napkin dipped in cold water. A plan frequently put into force by students is, to take a jug of cold water and to pour it from a considerable height upon the bare abdomen. This rough procedure often answers admirably, but it makes the patient and the bed in a frightful mess. I must confess I am very chary of wetting the clothes of a flooding patient more than I can possibly help. I have seen two cases of pelvic cellulitis occurring in women after flooding which I firmly believe were in a great measure brought on by their having to lie for hours in clothes soaking wet. I do not say that the douching from a height should never be done, as cases do arise in which the uterus will respond to no other stimulation, but I think it is better first to try more gentle means of applying cold.

Besides cold externally to the uterus, cold may be also applied to the vulva. It is generally done by means of napkins frequently dipped in cold water. In some cases I have seen good done apparently by wiping, in addition, the buttocks and back of the thighs with the wet napkin. Placing the patient's hands in cold water has also been found useful.

In the majority of cases, the external application of cold,

with or without other measures, suffices to stimulate the uterus to contract. In a few instances we may have to use cold internally. We may inject cold water into the uterus, vagina, and rectum. The injection of cold water into the cavity of the uterus has been employed with excellent result after all other means had failed. The nozzle of an ordinary Higginson's syringe should be directed through the os by the left hand, and the water pumped in by the right. If a case of hæmorrhage has been treated properly from its commencement, the intra-uterine injection will rarely be required. I do not believe also that it is totally unattended with danger. A medical friend told me that he once used the cold water injection into the uterus, and that the patient never rallied after it was done. Whether that was due to the great loss of blood or the shock of the injection, or both combined, it is impossible to say. In cases which require the internal application of cold, it would be as well to try first injection into the vagina, or the throwing up of a pint of cold water into the rectum. The injection of strong astringents into the uterine cavity has been recommended ; bad, indeed, must the case be in which simple water is not sufficient. If any astringent should be required, I should suggest taking up into the uterus, enclosed in the hollow of the hand, a piece of sponge dipped in a saturated solution of perchloride of iron, and smearing all the fundal portion with it.

Another way in which cold can be applied internally is to let the patient drink a glass of water as cold as it can be obtained. It very often brings on a strong uterine contraction, and at the same time rallies the patient.

REMARKS ON PROSTITUTION,

WITH A

VIEW TO THE ADOPTION OF MEASURES

FOR THE

CHECKING OF VENEREAL DISEASES.

By GIDEON DOLMAGE,

Deputy Inspector-General of Army Hospitals, and Medical Attendant to the Small Arms Factory and Military Clothing Depôt, Pimlico.

(Continued from page 329.)

We shall give a brief illustration of the camp-life of the miserable :—Not admitted within the camp precincts, she takes shelter in the hedges and ditches adjoining ; shelter it can scarce be called. Here, however, she spends her time day and night, and yields herself up to every kind of reckless abandonment and licentious debauchery ; when sick she goes to the workhouse, and should she be recovered it is too frequently only to return to her life of infamy and crime.

And these are the women with whom our soldiers hold carnal converse ; these the sources of disease whence emanates the deadly poison which destroys our young men even in the flower of their age and decimates our camps and barracks when *they are, in every other sanitary point of view, as perfect as camps and barracks could be rendered ;* these are the plague-spots in the midst of health, living masses of deadliest corruption, whose very breath is destruction and pestilence ; these, these are they whom we allow to prowl around our soldiers, excite their worst passions, and to open their lascivious arms to embrace them ; and, as the Egyptian Queen clasped the Roman Triumvir to his destruction, or the Iron Figure of the Inquisition the unahppy victim, they embrace their lovers only to destroy them.

For the sake of these poor women themselves, for the sake of our young men and soldiers, and of society at large, legal measures must be taken ; *acts of Parliament* must be passed relative to the arresting of this disease ; and these acts must be enforced with the utmost stringency.

We would propose the following measures ; and first, as regards the men :—That they should be encouraged to marry early. This might be effected by removing all obstacles to marriage, and by seeking to make the wife and children as comfortable as possible.

The wife and children, when it is at all in the power of the authorities, should be allowed to accompany the soldier, and *should be conveyed along with him at the expense of the Government ;* that, when it is not practicable for the children to accompany him, the most strenuous efforts should be made to send his wife with him.

The wife should be encouraged to accompany her husband by being provided with comfortable accommodation, either in the barracks (the plan to be preferred), or outside them in Government houses set apart for this purpose.

That there should be regular and strict medical examinations made of every soldier twice in each week.

That the soldier be held responsible for being drunk *when off duty* as well as when on duty, and if seen to be drunk should be at once brought home by his comrades ; and that, should he prove refractory, and not allow himself to be led or carried home, it should be made obligatory upon his comrades to at once give intimation to the guard.

That amusements, physical and mental, should be provided for the soldier, and that it should enter into part of his training to be instructed in at least the simple elements of education.

That ablutions of the entire body should be more frequent, and the places for such ablutions be more private ; that non-commissioned officers be appointed as inspectors, and be responsible for the carrying out of this regulation.

That men, immediately on finding themselves diseased, or suspecting the existence of any such disease, should present themselves before the medical officers for inspection ; and if any such disease were present, should be required to give up the address where it was contracted, as well as to point out the name of the woman who was the source of the contagion.

That regimental orders should be issued prohibiting any soldier from entering the house where such disease was taken, and that a heavy punishment, to be rigidly carried out, should be attached to any violation of such regimental orders.

That if a comrade or comrades be known to any one soldier, or to any number of soldiers, to have violated such orders, said soldiers be held equally culpable with the actual violator, unless they give up his name to the proper military authorities, having first warned him of his breach of discipline ; and finally, that it be laid upon the honour of every soldier to strictly carry out these regulations, and assist the authorities in the discharge of their duties.

Concerning the women we would say :—That they should not be allowed to be free agents, inasmuch as being diseased, and likely to communicate disease, they are public nuisances ; or even when free from disease, being at any moment, from the nature of their occupation, likely to become diseased and originators of disease, they are to be viewed in the same light—that is, as public nuisances, detrimental to the weal of the community at large.

To this it will be objected, that ours being a free country, we cannot impose any such restraint upon a subject. Were this so, we can only say that it would be a false kind of freedom, and would not in the cases of other diseases, infectious or contagious, be tolerated by the masses, since it would be a protecting of one to the injury of many, and would be, therefore, monstrously unjust ; but we deny that such is the spirit of our laws, and our denial is substantiated by reference to analogical instances. Is the baker allowed with impunity to sell bread adulterated in such a manner as to prove prejudicial to the public health ? or the butcher to vend or even expose for sale, meat which, if received in exchange for money and partaken of, would gender disease, and tend to shorten life ? Is it not made incumbent upon householders, landlord or tenant, to remove any source of malaria, contagion, infection, or anything likely to cause deterioration of public health ? Are parents free agents in the matter of vaccinating their children ? Are they not punishable by law if they omit to have this duty performed —a duty they owe not to their children alone, but to the State at large ? Assuredly there is not that freedom of which some in their ignorance of the spirit of our constitution make a boast—namely, freedom of one subject to the detriment of all others ; such freedom, we again repeat,

is wholly foreign to our ideas of liberty, and incompatible with our legal enactments.

No permanent good, we fear, can arise from mere bye-laws or police regulations; it will require an act of Parliament to check the spread of this formidable disease; and this act, when passed, will need to be executed with the utmost rigour in order to effect any diminution in the numbers of the diseased, or unless it be meant that the act itself should be a mere form. Such an act might not be misappropriately termed the "Prostitution Act."

We shall give a few headings of clauses which such a Bill should contain:—

First, there must be a full control of the authorities appointed for the inspection of prostitutes and brothels: secondly, officers with special charges: thirdly, registration of all women—name, age, personal appearance, occupation (independent of prostitution), family, native country, residence—all being entered in registry books and also upon a ticket which should be given to each woman and which she should be compelled to produce when it may be required by the authorities: fourthly, that all women be examined at least once in the week; no excuse being taken for an examination not being allowed: fifthly, that each ticket of registration contain all the regulations regarding prostitution, and all the above entries concerning the women individually, with any further entries that may seem fit to the authorities to be made from time to time; also, the condition of the women on last medical examination be specially noted, with any comments the medical attendant may think fit to append: sixthly, an order against her changing her residence, or being absent for any longer period than three days without the written permission of the inspector, or of the medical superintendent: seventhly, no lounging about or congregating in the streets or the public-houses or in the theatres, nor any attempt at plying her trade in the streets or in any other public places: nor, eighthly, be permitted to stand at the windows or doors of houses for the purpose of attracting visitors; nor should any permission be granted her to be out after nightfall: ninthly, a heavy penalty for drunkenness; for indecency in language, dress, or in any other way: tenthly, severe punishment of women who are not registered, and who, when registered but diseased, continue to ply their trade: eleventhly, a sufficient number of hospitals for the reception of such diseased persons, and an immediate admission into hospital granted them: twelfth, inspectors, &c., to be paid *by the tax levied upon prostitutes and brothels.*

As regards the houses, we would say:—Every house should be registered; the ticket of registry to be shown whenever desired by the authorities; severe penalties for all non-registered houses; keepers of registered houses to be held responsible for the freedom from disease of their *employées* and to be heavily fined when it is proved that any woman in any such houses shall have communicated infection; keepers immediately to send to hospital any woman diseased, or, at least, to give notice of such disease, and prevent said woman from having connection; that each house of this character should bear upon it a particular mark betokening its character.

In the vicinity of each camp or barrack there should be a sufficient number of lock hospitals, and such hospitals should be under the charge of the *military* authorities; military surgeons and assistant surgeons being *permanently* attached to such institutions; the pay and allowance of said medical officers being higher than if they were attached to regiments, or enjoying any other staff appointments.

The advantages of having those medical appointments permanent cannot be too highly commended, nor is it in this paper necessary to point these out, since they are apparent to all medical officers, and must arrest the attention of even non-medical observers.

The working of a system somewhat similar to the above may be seen from the following figures gathered at the Sifilicomio of Naples:—The percentage of disease had in the course of three years come down from 50 to 30. In 1861, 75 per cent. of patients were affected with chancres; whereas now there were only 29 per cent. The number of registered prostitutes in the first quarter of 1861 was 413; whereas in the last quarter of 1863 it was 1,475.

We would commend all Lock Hospitals to the earnest support of Government, feeling assured that they are one of the great means for combating this terrible disease and for ameliorating the horrible conditions dependent upon it; we commend them, confident that money expended in supporting them and in every other effort for the arrestment of this pestilence is laid out to the best advantage of the State at large, as well as of many individually, and is put out to the highest possible interest, as the health returns of our soldiers and of our working classes would demonstrate at no very distant period.

69 Bessboro' street, South Belgravia,
May, 1864.

HOSPITAL REPORTS.

KING'S COLLEGE.

Case I.—Lithotrity for the Third Time in a Middle-aged Subject.
Operation by Mr. Fergusson.

The first patient placed upon the operating table was the subject of stone in the bladder, and had been operated on twice before, when the stone upon each occasion was crushed and the fragments removed; on the present occasion likewise, Mr. Fergusson crushed the calculus, which was very soft in its composition, and was, he considered, quite a new formation, all the particles of the previous calculi having, at each time of crushing, been completely removed.

Case II.—Tying the External Iliac in a Patient upon whom the same Operation had been performed on the opposite side some time previously, Operator upon both occasions being Mr. Henry Smith.

This man is of strong constitution, and of that peculiar slender, "wiry" build indicative of strength; he is a carpenter by occupation, is a hard worker at his trade, is very temperate in his habits; he is about the middle age.

His history is as follows:—Some time since, he noticed a swelling in each groin, that on the right side being the larger; and as it continued to increase in size, he consulted Mr. Smith, who found the tumour to be an aneurism of the common femoral artery.

Upon the true nature of the swelling being ascertained, the man was admitted into hospital under care of Mr. Smith, who, in accordance with the views of modern surgeons, applied pressure and maintained it for three or four weeks, without, however, effecting any cure of the aneurism, and only occasioning the man a great deal of pain, both by the actual pressure and by the sloughing of the integument, consequent upon the pressure, and that too when it was applied with the utmost possible caution and with the nicest delicacy.

The pressure having failed, and the patient being anxious to have something done which would radically cure the affection and take away the constant jeopardy to his life, Mr. Smith thought it advisable to perform the ultimate operation, and accordingly put it into practice on the 11th of last August, by tying the external iliac artery. The result of this procedure was the happiest that could be desired. At the time of the performance of this first operation, there was a tumour in the left groin, of the same nature as that on the right side, but of a much smaller size; to this, pressure was applied for two or three weeks, but as its only effect was pain and distress, it was discontinued, and the man was sent out to regain strength and general tone to the system, being kept, however, under constant surveillance, so as to watch the course of the tumour, and to be able to operate for its removal at the time most opportune.

As the swelling on the left side grew steadily larger, the patient was readmitted into the hospital, but preferred to have the operation of tying the vessel performed, rather than again be submitted to the torture of compression. Mr. Smith, therefore, in acquiescence with the patient's own

desires, because these were in accordance with what was proper, that is, with the laws of established surgery, proceeded to tie the external iliac vessel of the left side, in the same manner as he had done that of the right; the only difference being as to the length of the incision, which, on the present occasion, was not carried so far upwards and outwards. The reason for thus limiting the line of incision was to obviate protrusion and descent of the intestine through the weakened walls of the abdomen, a condition which had already existed on the right side at the seat of the former operation. By having, however, a shorter incision, Mr. Smith hoped to prevent a hernia.

The patient being brought completely under the influence of chloroform, Mr. Smith beginning his incision somewhat internal to the centre of Poupart's ligament, carried it upwards and outwards towards the crest of the ilium for a distance of about four inches; having cut through the integument, he then, layer after layer, divided most carefully each structure, affording protection from the knife by either his finger or the director. The lips of the wound were held apart by the fingers of assistants or by means of the retractor, Mr. Fergusson taking charge of the upper lip, so as to prevent any slipping down of the intestines upon the knife of the operator.

At length, after the most careful dissection and manipulation, the artery was reached; and, lest there should be any mistake in taking it up, it was compressed by the finger to ascertain that the flow of blood was arrested throughout the entire limb by this compressing force. This expedient having been adopted, after a little further delicate dissection, necessary for the passing of the aneurism needle easily between the vein and artery, these vessels were separated sufficiently to admit the needle between them, which was then done from the inner toward the outer side of the body—that is, from the mesial line outwards; and its point having been brought out on the outside of the external iliac vessel, the ligature, with which the eye of the instrument was traversed, being seized with the forceps and drawn out so as to have a single coil around the artery, this latter was tied.

Another ligature was thrown around the epigastric artery, such a procedure being considered prudent as a guard against secondary hæmorrhage, which might otherwise possibly occur, owing to the contiguity of origin of the epigastric artery to the site of the ligature upon the external iliac. The wound in the abdominal walls was then united by the ordinary thread-interrupted suture, over which strips of wetted lint were laid, these being in turn covered with a towel, and all being then secured by a calico bandage.

In his remarks after the completion of the operation, Mr. Smith adverted to the rarity of such a measure as that he had just put into force, namely, the tying of the external iliacs of both sides in the same patient.

Mr. Tate had also performed this operation beside Mr. Henry Smith himself. The name of this latter gentleman is well known in connection with this operation, since he has on various occasions ligatured the external iliac artery on one side, and the common femoral on the other, in the same patient.

In November, 1846, Mr. Partridge, in a patient of 23 years of age, and suffering from aneurism of the common femoral, ligatured the external iliac; in January, 1849, the same was performed by Mr. T. Nunn, and for the same affection as in the case of Mr. Partridge. In August, 1850, Mr. Smith, the present operator, also tied this vessel, and for aneurism of the superficial femoral implicating the artery high up. The present operation was a modification of Sir Astley Cooper's.

CASE III.—DISEASE OF THE ANKLE-JOINT. OPERATION BY MR. FERGUSSON.

The history attached to this case is as follows:—Up to about nine months since, the patient enjoyed most excellent health, was stout and robust; but at that time, from no assignable cause, idiopathic inflammation attacked the joint, and the result was a constant discharge and pain, no doubt from disease of the bones, and which had rapidly deteriorated the health and enfeebled the sufferer.

The patient was in a very weakly condition when he presented himself at the hospital, but after being in the house a few weeks he rallied somewhat, and growing a little stronger, Mr. Fergusson thought it expedient to remove the source of the constant discharge and exhaustion.

Chloroform being administered and the vessels of the leg being compressed by Mr. Wood, Mr. Fergusson performed that operation usually known under the name of Pirigoff's modification of Syme's.

The foot having been removed, the integuments of the ankle-joint dissected up off the extremities of the tibia and fibula, the ends of these bones sawn off, a thin slice having been taken away from the divided os calcis, the flap containing the posterior portion of this bone was turned up to meet the superior lip of the wound, and was retained thus *in situ* by means of the interrupted suture. Scarcely any blood was lost, so tightly were the vessels compressed. The stump was enveloped with pledgets of lint and then in the folds of a bandage.

Mr. Fergusson considers this mode of operation preferable to Symes, both in its performance and in its results, at the same time that he holds in every respect the plan of removal introduced by Mr. Syme, to whom also is due the praise for originality of design.

It is incumbent on the surgeon not to leave too large a portion of the os calcis. In the present instance there was not much appearance of disease externally, though it proved on examination of the parts after removal that there was extensive erosion of the cartilages; the disease had not, however, penetrated deeply into the bones, as, indeed, it does very rarely.

CASE IV.—AMPUTATION BELOW THE KNEE-JOINT BY MEANS OF THE CIRCULAR METHOD.

The history is as follows:—The patient, an elderly man, but in the enjoyment of excellent health, was admitted into the hospital for disease of the ankle-joint and for a deformity of the leg, immediately above it, which rendered the limb worse than useless, inasmuch as it was unwieldy and cumbersome. This condition had arisen from a compound fracture of the bones, sustained about sixteen months previously; this was the second fracture of these bones, the first having occurred about ten years before.

By the more recent injury he had been confined to hospital eight or nine weeks, after which the existing deformity had gradually resulted, owing, without doubt, to the too early use of the newly-developed bone material thrown out for the uniting of the broken bones, whereby it had been made to yield under the superimposed weight of the body, and had allowed an incurvation of the foot and a bending outwards of the leg at the site of fracture.

These evils were caused by the man's having left hospital before the callus had become solidified; and results quite as disastrous supervened when a patient, after resection of the knee-joint, was removed from hospital before anchylosis had been fully established.

An example of this latter kind we lately had an opportunity of witnessing in the theatre of this hospital, where it was shown by Mr. Fergusson. It was that of a little boy upon whom the operation for excision of the knee had been some time previously performed; he had remained in the house for a certain length of time, but his friends, wearying of his stay in the hospital, had removed him; and the patient, thus deprived of the care of a medical attendant, had used the limb, had allowed it to assume an improper position, so that ultimately it was rendered completely cumbersome. To correct this state the operation had to be repeated.

We saw the patient six weeks subsequent to the second operation; the limb had been given its proper position, and had been made serviceable.

In the present instance, beside the deformity above mentioned, there was likewise disease of the ankle-joint. Elevating the limb, the patient being under the influence of chloroform, and the artery compressed firmly, Mr. Fer-

gusson passed the knife from the inner side of the calf of the leg outwards towards the fibula. This done, it was then carried in front of the bones, the direction being also from within outwards, so that the two incisions, made to meet externally, circumscribed the leg. The integuments of the calf were then dissected up from the calf itself, which latter, adopting the plan introduced by Teale of Leeds, it was not the intention of the operator to comprehend in the flap for the covering of the face of the stump, the only parts used for such a purpose being the integument and the subjacent cellulo-adipose tissue.

The procedure, in amputation, of setting aside the muscles altogether, and using only the integument for a flap, has been attended with most excellent success, so as to warrant its adoption in preference to the old methods.

In theory, however, it seems best to have a quantity of muscle as a pad or cushion of support for the extremity of bone, and it appears awkward to have as a covering merely the skin and cellular fascia; but experience demonstrates, that though for the first twelve months the muscles seem of use, yet after the lapse of ten or twelve years they become completely atrophied—so much so, indeed, as to leave the rounded extremity of the bone covered only with the skin and some little fibrous tissue developed subsequently to the operation. The skin flap may be varied at the pleasure of the operator. The wound was brought together by the ordinary thread, interrupted suture, and then dressed with pledgets of lint, kept in their place by the fold of a calico bandage.

CASE V.—SECONDARY AMPUTATION FOR THE RE-FASHIONING OF A BAD STUMP.

This case was very appropriate to the present occasions, since it showed the ill result of leaving a quantity of muscle on the posterior flap.

The operation had been no doubt admirably performed, and there was no blame to be attached to the operator; but the fault lay in the operation itself, by which the bulky calf was preserved, turned up over the face of the bone in the hope that it could be kept there, but had, contrary to what was desired, slipped downwards and backwards away from the upper or anterior flap and from off the end of the divided bone.

Mr. Fergusson said that he recollected Mr. Liston, who was the great advocate for flap operation, often expressing his regret that he had left too large a flap of muscles.

Standing on the right side of the patient, Mr. Fergusson entered the point of the knife on the side of the stump farther away from him, and then drawing its edge across the entire face of the stump encircled by his line of incision a portion of the soft tissues of the limb, as well as the extremity of the bone, both of which were removed, in the former there being included the cicatrix of the wound of the first operation.

The posterior or inferior flap was then dressed by having dissected away the fibrous tissue which had been developed in it and whatever of muscle had remained; this done, it was brought over the freshly sawn bone, and united by the thread suture to the anterior flap; the usual mode of dressing being then put into practice.

This case presents a good illustration of the difficulty of arresting the hæmorrhage from the vessels divided in this situation, owing to their retraction within their fascial sheaths, as it was some time before they could be seized and drawn outward in order to have a ligature thrown around them for their deligation.

ABSINTHE.—M. Marcé recently sent in a paper to the Institute of France on the effects of the intoxicating fluid called absinthe, which he states to be different from those of any other spirit; brandy, for instance, does not give rise to the fearful hallucinations and utter prostration of the nervous system usually consequent on the excessive use of absinthe. Dr. Marcé's experiments on the essence of wormwood show that it is a stupefying poison, which produces a sense of terror even in animals.—'Journal of Practical Medicine and Surgery.'

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XV.

AMMONIÆ LIQUOR FORTIOR AND LIQUOR AMMONIÆ.—A slight alteration has been made in the strength of these solutions of ammonia. The difference, however, is so small as to be of little practical importance. The specific gravities of the old and new solutions are as follows:—

	Ph. Lond.		Ph. Brit.
Liquor ammoniæ	0·960	...	0·959
Liquor ammoniæ fortior ...	0·882	...	0·891

It would, of course, be inferred from the specific gravities given, that the liquor ammoniæ fortior of the British Pharmacopœia is weaker than that of the London College. Nevertheless, the descriptions given in the two cases represent just the contrary. The London Pharmacopœia describes its solution as containing nearly 30 per cent. of ammonia; the British Pharmacopœia specifies that its solution contains 32·5 per cent. All chemical authorities are agreed that the percentage of ammonia and the density of the solution bear a direct and constant relation to each other.

There can be no doubt of the fact, therefore, that a solution of ammonia having a specific gravity 0.891 will really contain less ammonia than a solution of a density 0·882.

One of the Pharmacopœias must consequently be in error in stating the percentage of ammonia; the probabilities, however, appear to be in favour of the British Pharmacopœia being right. The inconsistency has perhaps arisen from the compilers having in each case consulted the tables which are given in chemical works of the specific gravities of solutions of ammonia of various strengths. Tables of this kind have been constructed by Dalton, Sir Humphry Davy, Dr. Ure, Mr. Griffin, J. Otto, L. Carius, &c., but, unfortunately, they none of them exactly agree. The discrepancy between the older ones and those of more recent publication is especially great. Thus, the statement of the London Pharmacopœia agrees very well with the table given by Davy, but is quite inconsistent with the figures of Griffin or Carius. The specific gravity of a solution of ammonia containing 32·5 per cent. is variously represented by these different authors as follows:—

		Sp. Gr.
Sol. of Ammonia, 32·5 per cent.	Dalton.....	0·86.
	Davy	0·875.
	Griffin.....	0·8839.
	Carius.....	0·8918.

It will be seen that the British Pharmacopœia agrees perfectly with the figures given by Carius; and as the latter is, we believe, the most recent authority, he is probably the most worthy of reliance. According to his table, the liquor ammoniæ fortior of the London Pharmacopœia must contain about 36 or 37 per cent. of real ammonia; but the British Pharmacopœia avoids all uncertainty regarding strength, by indicating the amount of oxalic acid necessary to neutralise a given volume of the solution.

Liquor ammoniæ fortior is prepared by passing ammoniacal gas into water. The ammonia is liberated by making a mixture of sal-ammoniac, lime, and water, and applying heat. A reaction occurs, in which chloride of calcium, water, and ammonia are formed—

$$NH_4\,Cl + Ca\,O = Ca\,Cl + HO + NH_3.$$

The ammonia volatilises and is then passed through a series of Woulf's bottles. The first bottle contains a very little water, and is reserved for purifying the gas from impurities mechanically carried over. The remaining bottles contain the water to be saturated.

The impurities of liq. ammoniæ are chiefly carbonic acid and empyreumatic matter. The former may be absorbed by the exposure of the liquid to the air; it may also be present when the lime used in the process contains a great deal of carbonate. It may be readily detected by the addition of a little lime-water or solution of chloride of calcium. The empyreumatic matter is derived from the impure ammoniacal salt which is sometimes used. Its presence may be recognised by the tinge of colour it communicates to the liquid, and also by the peculiar odour it imparts.

Lastly, if common water has been used in the preparation of the liquid, it will contain sulphate and chloride as well as lime. The lime is known by a solution of oxalic acid; and the other impurities, by first adding an excess of nitric acid, and then testing with chloride of barium and nitrate of silver. Metallic impurities, as lead and copper, are discovered by the action of sulphuretted hydrogen.

AMMONIÆ PHOSPHAS.—Some amount of uncertainty appears to exist as to the salt really intended by the compilers of the Pharmacopœia to be used as phosphate of ammonia. It has been even suggested that there is an error in the descriptions given, and that a different compound is really meant. The principal reason for this supposition is the fact that the salt actually described is so liable to change, that it can scarcely be got at all in a definite condition, and certainly cannot be kept for more than a few hours.

There are three compounds of phosphoric acid and ammonia known to chemists; they have the following composition:—

Triphosphate . .	3 NH_4O, PO_5
Diphosphate . .	2 NH_4O, HO, PO_5
Monophosphate .	$NH_4O, 2\,HO, PO_5$

The first of these is produced when phosphoric acid is treated with a considerable excess of ammonia. The salt at once separates as a crystalline magma. The combination, however, is described as being so feeble, that one atom of ammonia passes off with almost the same facility as the adhering moisture; consequently, by simply drying the salt, it is mainly converted into the diphosphate.

The diphosphate is the salt commonly met with and employed; it is, indeed, the most stable and definite of the compounds of phosphoric acid and ammonia. It is generally prepared by mixing a solution of superphosphate of lime with carbonate of ammonia; a precipitate is thrown down and the phosphate of ammonia remains in solution. It may be readily obtained in large and distinct crystals. By exposure to air this salt effloresces and at the same time loses a little ammonia. When exposed to a red heat, it slowly parts with the whole of its ammonia, and glacial phosphoric acid is ultimately obtained.

There is one objection which may be urged against the use of this salt in medicine: it is stated that it is frequently contaminated with arsenic. Phosphate of ammonia is made commercially, as we have said, from superphosphate of lime. The latter substance is manufactured very largely by treating burnt bones with sulphuric acid, cheap oil of vitriol, which contains abundance of arsenic, being employed for the purpose. The subsequent parts of the process for the preparation of phosphate of ammonia are not capable of removing this impurity, and its presence may consequently be detected in the salt. Such phosphate of ammonia, of course, should not be used in pharmacy; it is sufficiently easy to prepare the salt in a state of purity.

The monophosphate has no application, and is not of any importance. It is only interesting in a purely chemical sense.

The phosphate of ammonia of the British Pharmacopœia is not the salt now generally known by that name, but is the triphosphate just described. This is clearly indicated by the formula which is given—$3\,NH_4O, PO_5 + 5\,HO$—and also by the test appended in the materia medica. The test directs that twenty grains of the salt shall yield 11·44 grains of calcined phosphate of magnesia, a quantity exactly corresponding to the formula given. The other characters described do not, however, specially belong to this salt. On the contrary, in one respect, they are rather suggestive of the diphosphate; for the salt is stated to occur in colourless transparent prisms.

The process given for its preparation is very simple. It consists in adding eight ounces of strong solution of ammonia to twenty ounces of the diluted phosphoric acid. A crystalline precipitate forms, which is to be dissolved by a gentle heat, and the solution then allowed to crystallize. The proportion of ammonia ordered is greatly in excess of the quantity theoretically required; this, in fact, is not only necessary for the formation of the salt, but it is also beneficial in causing it to separate out at once as a crystalline precipitate.

It is strange that the authors of the Pharmacopœia should have thus ordered a salt to be used in medicine which can hardly be separated from the liquid in which it forms without decomposition, and which certainly cannot be kept many hours. Practically, indeed, it is the diphosphate which must be used; and there is no reason why it should not have been made the officinal salt, especially as its properties are well known, and the process here given is equally applicable to its preparation.

REVIEW OF BOOKS.

The Science and Art of Surgery. By John E. Erichsen, Professor of Surgery and of Clinical Surgery in University College, and Surgeon to University College Hospital. Fourth edition, pp. 1277. London: Walton and Maberly. 1864.

The work before us has had a large share of success, especially when it is taken into consideration that since the first edition was published, nearly eleven years ago, a number of surgical treatises have been sent forth either in the form of new editions of old and well-known books, or as entirely new works. The smaller text-books have not lost any of their popularity, and the bulky tomes of Cooper and Holmes, issued in parts, have deservedly attracted the attention of all surgical students; but, nevertheless, we now find Mr. Erichsen's treatise sent out for a fourth time, and in a more voluminous form than before, the author telling us that "every page has been carefully revised. Some chapters have been, in a great measure, re-written; new woodcuts have been introduced; and the text has been considerably enlarged."

Even since the last edition was written there have been many improvements in the practice of surgery, and the author has not lost sight of them. The method of performing amputations according to the plan proposed by Mr. Teale, of Leeds, receives full consideration at his hands, and the important subject of aneurism and its treatment is discussed at length. The use of compression still finds as much favour as ever in the hands of Mr. Erichsen, and the merits of flexion and digital compression are brought under notice—the latter plan, perhaps, not quite so prominently as it might be. We believe, however, that it has not been extensively tried in this country; and probably the unsuccessful results following its employment in the recent case of a well-known member of our profession, may retard its further use for a period at least. Mr. Fergusson's method of *manipulation* has also its share of consideration.

The recently-revived method of arresting hæmorrhage by acupressure is considered fully and fairly by the author, who, like every other surgeon of experience, recommends it as safe when small vessels are dealt with, but is too prudent to depend upon it when the large arteries are concerned.

The question of operation for malignant disease is one which has been much discussed of late years, and Mr. Erichsen devotes considerable space to it. His summing-up is decidedly in favour of operating for malignant disease in suitable cases, and he very properly states that the use of chloroform materially affects the question, and that as all the pain of the operation can be removed, we are justified in operating in instances where otherwise we should perhaps hesitate in doing so.

With reference to the question of excision of the hip and knee joints—so warmly discussed, and we may say so bitterly opposed, a few years since, though not by Mr. Erichsen—the author is evidently strongly in favour of operating in certain instances. For the treatment of club-foot, tenotomy is still recommended; and Mr. Barwell's novel practices, in connection with his "cure without cutting of tendons," are not so much as noticed.

With regard to the performance of tracheotomy in croup and diphtheria, the author, perhaps, is not so favourably disposed to it as many other surgeons are, especially among our brethren on the other side of the Channel, and he states that "the general experience of British surgeons is unfavourable to it." Doubtless this was the case some years ago, but of late years there has been such success attending tracheotomy, especially when performed in croup, that opinions are very much changed with regard to it. As to diphtheria, Mr. Erichsen himself says, that if we can only save one life in a hundred, we should be justified in performing the operation.

With reference to another important subject which has lately been discussed—viz., the formation of an artificial anus in instances of insuperable obstruction of the large intestine—Mr. Erichsen is in favour of operating; and he prefers the method of Amussat to that of Littré, for reasons which he has given at length at pages 1030 and 1031. Some observations are directed in this work to the diseases of the breast and axillary glands in the male, and two striking illustrations of large tumours are inserted. The radical cure for hernia has a proper share of attention devoted to it, and the modern proceeding of Mr. Wood, of King's College Hospital, is described at length.

The only novelty of late years in connection with stone in the bladder is the re-introduction of the median operation, which is considered at some length. Mr. Erichsen seems to be favourable to its performance in the adult, when the stone is not large, but very judiciously puts his veto upon its introduction in the case of children, because the lateral operation of lithotomy under the age of puberty is a very successful proceeding.

We have now simply pointed out those subjects which are novel or are more fully discussed in this present edition. For those who already possess the book, little more is required at our hands, but to those to whom it is new, we strongly recommend it as one of the best treatises on Surgery in our language. Its appreciation in foreign countries may be surmised, from the circumstance that it has passed through two editions in America, that it has been translated into German by Dr. Thamhayn, of Halle, and that it is now in the hands of a French editor.

Mr. Erichsen possesses the advantage of teaching and practising surgery in the school where he himself was educated, and thus he has had the opportunity of inculcating upon the present generation of students and practitioners, the precepts which he derived from the distinguished teachers who occupied the same position which he now so worthily fills. The fame of Liston, cut off in the prime of life, of Samuel Cooper, dying at a ripe old age, and of Morton, disappearing almost in youth, still lingers in the lecture-rooms, the wards of the hospital, and the operating theatre, of University College: and their rules of practice, some the fruits of matured experience, and others the results of quick and inventive genius, are still impressed upon the minds and illustrated before the eyes of the existing race of students of that institution. Mr. Erichsen has had the good fortune to combine in his own person the dexterity of a felicitous operator, with the pen of a ready writer and the ability of a successful teacher, and in him, therefore, the school of University College loses nothing of its former renown. His 'Science and Art of Surgery' is an admirable compendium of the existing state of Surgery in the civilized world, and his industry in collecting information from all available sources is as conspicuous as the fairness with which he treats the labours of his contemporaries. The great strides made in the operative and conservative branches of the art have all been recorded in his pages, while the modern department of pathology in its relation to surgery is fully elucidated. On the principle of presenting to the eye a series of images which may more fully impress the understanding than mere verbal descriptions, the text is accompanied by no less than five hundred and seventeen engravings on wood, all executed with great fidelity, and illustrating every department of surgery, from the microscopic structure of tumours to the mechanism of instruments, the appearance of diseased or distorted limbs, or the successive steps of surgical operations.

We cordially recommend Mr. Erichsen's work in its present enlarged and improved state to the notice of the Profession.

OBITUARY.

GEORGE FRANCIS COOPER, M.D.

This gentleman, after less than three weeks' illness, has just been hurried away from amongst us. He was the eldest son of one of those noble, hospitable, and distinguished practitioners of the olden time now fast disappearing; but Mr. Cooper, who still remains to lament the loss of a son and partner, is active, energetic, and the worthy representative of the Society of Apothecaries at the Medical Council.

The subject of this memoir was born at Brentford in 1827, was educated at Guy's Hospital, and, after passing through the usual ordeal of Hall and College, in the year following (1849) took his degree at St. Andrews. There was an excellent practice waiting for him, upon which he quickly entered, and obtained the confidence of the patients which had already been so justly accorded to the father. He was of a peculiar disposition, and, unless well-known, a natural shyness of obtruding himself might have been mistaken for sullenness; but the writer of this (an old friend) can state, that under that brusque exterior there always existed a deep feeling of sympathy for those in affliction, and a heart full of kindness for all who needed consolation. His talents were of no mean order. He had performed several operations successfully, which might have been sent to the London hospitals from so short a distance as Brentford; but he looked upon his patient's welfare as the first desideratum, and he considered that the circumstances attending removal were frequently coupled with risk to the patient's life.

Dr. Cooper was a most extraordinary muscular man, of fine proportions, and well made, with all his senses in their fullest vigour. He was a captain in the local volunteer corps, and had held a challenge cup two years in succession. His feats of agility were most remarkable; indeed, it is feared that his unwonted activity was probably the cause of his untimely end. On the 18th of April he was attacked at the lower angle of the the popliteal space of the right leg with pain, for which it was difficult to account. He was confined to his bed at once, and in a few days it was evident that there was phlebitis of the popliteal and femoral veins. The inflammation gradually crept up the course of the circulation, until œdema and other symptoms showed unmistakably that as far as the vena cava there was an impediment to the passage of the blood. He was seen several times by his former teachers, and most carefully tended by his old and valued friend, Dr. Willett. There was every reason to hope that by quiet and time he might be restored to health; but on last Sunday week, owing to some excitement, a portion of the plug in the vessels became detached, and in less than an hour he ceased to breathe.

A post-mortem examination revealed a large loose clot in the right ventricle of the heart, and broken clots of the same character in the pulmonary arteries; the veins of the right lower extremity were filled with coagula adherent to the vessels, and inflammatory deposit around them. It is a circumstance worthy of note that Dr Cooper, in the last half-hour of his existence, stated that something had broken off from a vein, and that he felt it pass upwards to the heart, thus perfectly diagnosing the cause of his own death.—'Lancet.'

THE MEDICAL CIRCULAR.

WEDNESDAY, MAY 25, 1864.

AMENDMENT OF THE MEDICAL ACT.

Although the recent discussion in the Medical Council on the Amendment of the Medical Act has not been attended with any immediate result, yet the opinions elicited have been of sufficient public importance to demand the careful attention of the Profession. It is notorious that the act of 1858 is a most imperfect one, and even some of the highest legal authorities have declared their inability to understand its provisions; and it is therefore essential that some steps should be taken to render it intelligible in its language, and efficacious in its operations, with the double view of protecting the legitimate practitioner in his just rights, and of protecting the public from the incompetence of empirics. The whole subject of the proposed amendments to the present measure has been under the consideration of the three branch councils respectively, representing England, Scotland, and Ireland; and while the Scotch and Irish branches have both recommended some alterations in the existing law, the English branch has come to the conclusion that it is inexpedient at present to move in the matter.

The Irish branch are desirous of amending the Act in such a manner as to abolish the status of the unqualified practitioner, who is distinctly recognised in the present Act, the preamble of which sets forth that "it is expedient that persons requiring medical aid should be able to distinguish qualified *from unqualified practitioners*;" whereas, the better plan would be to alter the preamble by stating that it is necessary, for the safety and protection of the public, to secure adequately-educated practitioners in medicine, surgery, and pharmacy, thus ignoring altogether the ignorant pretender. Another strong point in the Irish scheme was the proposed introduction of pharmacy into the Bill, and an enactment for the compulsory examination of chemists and druggists throughout the kingdom. This change is speciously supported by the arguments that Ireland already possesses some powers of this kind, although, from want of funds, they are in abeyance; and that while stokers, engineers, and pilots are all obliged to undergo examination, persons who are engaged in the sale of drugs, many of them of a poisonous nature, are subjected to no examination at all. A third feature in the Irish prospectus, warmly insisted upon by Dr. Corrigan, was the necessity of enforcing an adequate preliminary examination on the aspirants to medical licences, and of fixing a minimum in this respect, which shall be binding on all the examining bodies. It was also urged that all quack medicines should have their composition stated, which is done in the case of ordinary patents, the proprietors of which are protected by the law.

The Scotch branch appear not to care much about the chemists and druggists, the condition of pharmacy in Scotland being in a somewhat undefined position. The fact is, we believe, that the great mass of practitioners in Scotland make up and supply their own medicines, the exceptions being in the large cities, where chemists and druggists dispense the prescriptions of the physicians. Thus, what is called general practice is pretty much the same in Scotland as in England, though it is probably less remunerative in the former country. Nor are our Scotch councillors very particular about the preliminary education of the future medical practitioner. In fact, the medical student may, or at least might, enter at a Scotch University for the study of medicine without having undergone any preliminary examination whatever; and it is a well-known joke in bygone years, that some graduates have been unable to translate the Latin of their diplomas. Such times are, however, it is hoped, long passed; but still, the Scotch schools of medicine are by no means so particular as they might be in this respect, and even in the universities, preliminary education is not sufficiently encouraged. Indeed, we believe that we are stating only the truth in affirming that even now the Scotch Universities do not require their classical and mathematical examinations to be passed until the student has half completed his medical studies. But on some points the Scotch branch were sufficiently emphatic, and they asked from the Legislature an interpretation of the language of the Act as it now stood; and assuming that its object was to enable persons to distinguish qualified from unqualified practitioners, they maintained that it was impossible, or very difficult, for the public at present to make the distinction. If any person was justified in calling himself a doctor, and placing his title over his door, whether qualified or unqualified, how were the public to know the false from the true? It was, therefore, necessary that all qualified practitioners should be registered, and that no person whatever should be allowed to take or use any medical title without registration.

Such, generally speaking, were the views put forth by the Irish and Scotch branches of the Medical Council upon the amendments to the Medical Act, though we do not profess to state that all the members of each branch entertain the same views as their colleagues and compatriots. The English branch, however, seeing nothing but difficulties in the way of fresh legislation, has come to the resolution of doing nothing at all. This branch, whose views, by the way, are expounded, and very ably, by some of our Scotch brethren located in England, insists that it would be useless to apply to the Legislature for increased powers at the present moment, especially when the members of the Council are not agreed among themselves as to what alterations are desirable. No amended act would have any chance of success if intrusted to the hands of a private member of Parliament; and if the Home Secretary were consulted on the subject, his first question would be, whether the Council were unanimous in their demands, and whether the Profession generally supported their views: and unless these questions were satisfactorily answered, no Government would take charge of the Bill. Again, it might happen that if the question of amendment of the Medical Act were agitated in Parliament, the Profession might lose what it had

already obtained, and its condition rendered worse than before. Already the power of striking off from the Register the names of persons who had acted in an infamous manner was fully conceded to the Medical Council by the law, and this privilege might perhaps be withdrawn. As to the question of Pharmacy, it was a very difficult one; and any attempt to settle it would give dissatisfaction both to the Profession and to the chemists and druggists. With regard to the suppression or the discouragement of illegal practice, it would be utterly useless to ask for any powers for this end; because many members of both Houses of Parliament, and some of the highest people in the land, were the direct and avowed supporters of quackery of various kinds. In reference to the questions of education and examination, the English branch probably thought that there was not much to be desired in the way of alteration, especially in a country where the distinction of Medical ranks is not held to be an evil, but an advantage. At the Universities of Oxford, Cambridge, and London, the *alumni* may get, and *do* get, an excellent education, both general and medical, and the degrees of all these bodies are held in just and general esteem. The Colleges of Physicians and Surgeons educate men sufficiently in all grades of the Profession, those who wish to attain to the higher degrees being enabled to do so if they please; while the two Colleges just named and the London Society of Apothecaries grant very respectable licences to the great body of what are called General Practitioners. In England the different grades of the Profession have been conventionally agreed upon, and the system of a division of labour thus effected seems to work well in practice. Such are, or seem to be, the views entertained by the English branch; and they are not without weight.

The conclusion of the whole discussion, however, is, that the matters in question are all postponed; and we can only add the resolutions themselves, applying to the subjects of Pharmacy and amendment of the Medical Act. On the question of legislating for Pharmacy, it was moved by Dr. Corrigan, seconded by Dr. Quain, and agreed to:—

"That a communication be addressed to the Secretary of State for the Home Department, drawing his attention to the present defective state of the law regarding the practice of Pharmacy, under which any person, however ignorant, may undertake it; and expressing the opinion of the General Medical Council, that some legislative enactment is urgently called for to insure competency in persons keeping open shops for dispensing medicines and for the compounding of physicians' and surgeons' prescriptions."

On the amendment of the Medical Act, it was moved by Dr. Alexander Wood, seconded by Dr. Sharpey, and agreed to:—

"That the Council, while appreciating the labour and care bestowed by the Medical Acts Amendment Committee on the heads of a Medical Bill proposed in their report, regret that it is impossible, at this late period of the session, to enter on the full consideration of so wide and important a subject. That the Council request the Branch Councils, in the interval between this session and the succeding one, to consider how Clauses 20, 31, and 40 of the Medical Act could be best amended. That the Council resolve to appoint an early day, at their meeting next session, for the consideration of the whole subject."

SUMMARY OF THE WEEK.

THE BRITISH PHARMACOPŒIA.

As we have received numerous inquiries as to the 'British Pharmacopœia,' more particularly with reference to the probability of a new edition and the disposal of the present one, we think it right to state, for the information of the Profession and the public, that there is no intention whatever of recalling the present edition, which has been extensively sold and distributed over the globe, wherever British commerce or the British arms extend. The new edition, which may be expected to appear in about a year, will merely supply the want caused by the exhaustion of the present issue, and it will, of course, be revised and corrected in accordance with the advance of science, as any other scientific work would be. The new editor has been nominated, but as his appointment is not yet officially confirmed, we withhold his name for the present. He is a gentleman who is thoroughly acquainted with theoretical and practical chemistry and with all the details of pharmacy; and under the supervision and direction of the gentlemen appointed as the Pharmacopœia Committee, namely, Dr. Burrows, Dr. Sharpey, Dr. Quain, Dr. Christison, and Dr. Apjohn, he will no doubt exercise his responsible functions to the satisfaction of the Profession. We may here take occasion to state that the defects of the 'British Pharmacopœia' have been enormously exaggerated, and that, considering the great difficulties incident to its preparation and publication, it is a very able work. That it should have excited criticism is only what might have been anticipated: that it should be pronounced faultless is more than can be expected of any human work. That the action of medicines will always be strictly canvassed is a matter of certainty, and it is equally certain that opinions will differ as to the efficacy of particular drugs; and in a necessarily shifting science like chemistry, it is obvious that the most learned authorities will differ as to the atomic constitution of many chemical compounds. The acute criticisms contained in the pages of some of our contemporaries will no doubt advance the interests of science, and assist the new Editor of the Pharmacopœia in the revision of the work; and the able and elaborate articles which we ourselves are publishing, while they fully expose the defects of the present edition, are making known a multitude of facts with which all medical practitioners would do well to make themselves familiar.

THE 'BRITISH MEDICAL JOURNAL,' THE 'MEDICAL CIRCULAR,' AND THE MEDICAL COUNCIL.

We have been called upon to apologise to the 'British Medical Journal' for transgressing the rules of propriety in accusing that Journal of having made a positive misstatement in reference to the proceedings of the General Medical Council. We should be most happy to apologise if we were in the wrong, but such is not the case. The exact words in the 'British Medical Journal,' to which we took exception, were the following, and we quoted them

at the time :—"The College of Surgeons of England and the London Society of Apothecaries offer a continual opposition to the carrying into effect of the recommendations which a majority of the Medical Council has deliberately approved. This opposition is the more painful, when contrasted with the readiness with which other corporations have brought their regulations into the strictest conformity with the recommendations of the Council." Our own remarks were : "We have received and perused the whole of the minutes of the meeting of the Medical Council, and we have failed to ascertain that the Society of Apothecaries has ever placed itself in opposition to the Medical Council, on the subject of Medical Education, whatever the College of Surgeons may have done. So much for positive misstatement." We repeat, that the 'British Medical Journal,' on this point, made a positive misstatement, though, on the assurance of the Editor to the contrary, we are willing to allow that it was not a wilful one. We took the pains, at the time, to inquire into the subject, and we found that the Society of Apothecaries had throughout strictly complied with the recommendations of the Council: they had required of the candidates for their licence four years' attendance on lectures and hospital practice, and their published Regulations for 1862 distinctly insist upon such attendance.

But it so happened that the other corporations, so far from conforming to the recommendations of the Medical Council, had positively disregarded them, and headed by the College of Surgeons, *and sanctioned by the Council itself*, had returned to or maintained their previous regulations; and the Society of Apothecaries, therefore, had no choice in the matter but to rescind their regulations published in 1861 and 1862, and to require only three years' attendance on lectures and hospital practice; and in so doing, they *followed* the College of Physicians of London, the College of Surgeons of England, and nearly the whole of the Medical Corporations in the United Kingdom, the exceptions being one or two of the Scotch Universities, which, from the peculiarity of their constitution and the short period of the year which they devoted to lectures and hospital practice, had always required four *half-years* of attendance, equivalent to *two years*. The following letter, addressed by Mr. Upton, the Clerk to the Society of Apothecaries, to the General Medical Council, and published in the Minutes of the Council, explains in brief, but explicit language, the truth of the case :—

Apothecaries' Hall, London, E.C.
3rd March, 1864.

SIR,—I beg to hand you enclosed, a copy of the regulations of the Court of Examiners, which will be found, I understand, to be in exact accordance with the recommendations and resolutions of the General Medical Council, with the exception of the five years' pupilage, which is rendered compulsory by the Apothecaries' Act of 1815.

I have the honour to be, &c.,

Dr. Hawkins, Registrar of the General Medical Council.

ROB. B. UPTON, Clerk to the Society.

How the inability of a corporate body to repeal an Act of Parliament can be construed into a continual opposition to the carrying out of the recommendations of the Council, we are quite at a loss to conceive.

Having thus laid the real facts before the Profession, we can only repeat that we made ourselves fully acquainted with them before we wrote; and if our contemporary had done the same, the present controversy would have been unnecessary. As to the other charges we made against the 'British Medical Journal,' such as wilful exaggeration, we think they were quite justifiable when we found that a writer in that Journal had set forth, as the necessary courses of lectures to be attended by the medical student, a host of specialities and subdivisions of subjects, which, if a medical man, he must have known were not distinct from one another, except for the purpose of arrangement in a text-book.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

DR. G. JOHNSON commences a lecture "On the Laryngoscope," delivered lately at the College of Physicians. The object of his lecture he states to be his desire of showing that the difficulties of laryngoscopy are few, and may be overcome by a little practice and perseverance, and that there is no reason why the art of inspecting the larynx should be practised only by a select few, and converted into a specialty. Dr. Johnson refers to the invention of the instrument by Dr. Babington, who described it in the year 1829; the discovery of autolaryngoscopy by M. Garcia, during his physiological researches on the human voice; and the application of the laryngoscope to the diagnosis and treatment of disease by Czermak, to whose labours in this field warm commendation is ascribed. The rest of Dr. Johnson's lecture is devoted to the description of the apparatus for laryngoscopy, the difficulties sometimes attendant on its application, and the best methods of overcoming them.——MR. T. HOLMES continues his "Contributions to the Practical Surgery of Diseases of Childhood," his present subject being "Congenital Innocent Tumours: their Diagnosis and Treatment." It has happened to Mr. Holmes to meet with this kind of tumour six times in the course of four years, and he therefore considers that the disease cannot be a very rare one. The tumour in question is developed before birth; sometimes grows very rapidly in the early days of life, so as to threaten to prove fatal either by exhaustion or by the pressure of surrounding organs; but as it wants the essential characters of cancer, it cannot be classed with that disease, and, indeed, its constituents appear to be only some fibrous tissue, a few free nuclei, and a large quantity of fat. Mr. Holmes describes three cases of this affection, in two of which the children died without any operative means having been resorted to, and in the third the tumour was removed and the child recovered.——Dr. EDWARD SMITH continues his papers on "Dietary in Disease," his subject being obesity. He shows that it is not always safe to reduce the size of the body, as a certain amount of deposited fat is natural to man and to all animals living on a mixed diet. The rules laid down

for diminishing obesity are drawn from chemical considerations, exercise being enjoined, fats, sugar, and starch being restricted in quantity, beer and spirits forbidden, and meat taken three times a day.

THE 'MEDICAL TIMES AND GAZETTE.'

DR. GEORGE HARLEY continues his lectures "On the Urine and Diseases of the Urinary Organs," his present subject being uric acid, which he describes in its chemical and physiological relations. The quantity of uric acid excreted is greatly influenced by the nature of the food, and even by the time of the year, more being excreted in winter than in summer. The urine of human infants at the breast is devoid of uric acid, while that of sucking calves contains it. Uric acid in healthy urine is combined with the alkaline bases—soda, potash, and ammonia—and all the salts so formed are in a state of solution; but if they should happen to be in excess, or the water of the urine should be diminished, they are deposited in an amorphous state.——DR. J. W. OGLE continues to describe his series of "Cases of Softening of the Brain and Spinal Cord," the cases being of a very miscellaneous character, and the symptoms during life being often anomalous, but the post-mortem examination revealing softening of the cerebral matter.——DR. EDWARD DEWES relates a "Successful Case of Ovariotomy in a Person Sixty-seven Years of Age." The operation was performed by Mr. Clay, of Birmingham. This patient is said to be the oldest on whom ovariotomy has been performed in England, although a similar case, followed by recovery, is said to have occurred in America.

GENERAL CORRESPONDENCE.

IS MERCURY A THERAPEUTIC AGENT?

To the Editor of the Medical Circular.

SIR,—Will you do me the favour to permit me to reply to the interesting criticisms of my opinions, made by two of your correspondents, in recent numbers of your most impartial journal.

First, allow me to thank Dr. Griffith for his letter contained in the MEDICAL CIRCULAR of April 6th, and to attempt to reply to some of his questions. He says, "I would ask Dr. Drysdale if he has never heard of mercury being prescribed in the morbus coxæ even of scrofulous subjects, and prescribed with most beneficial results;" and he adds, that a patient of Dr. Walshe's, in Dublin, had recovered from tabes mesenterica under doses of hydrargyrum cum cretâ.

In reply to this question of Dr. Griffith, I have to say that I have very often heard and read of mercury producing cures in every disease, scrofulous, inflammatory, &c. Indeed, when in Dublin, I remember that it was thought by some to be beneficial in cases of acute albuminuria. But I believe I am only speaking the general opinion of London physicians at the present moment, when I state that mercurials are considered as quite counter-indicated in all states of the constitution coming under the category of scrofulous, whether hip-joint or other disease. I believe, indeed, that this is one of the points on which there is considerable unanimity of opinion. As to the case of tabes mesenterica said to have recovered *propter* doses of hydrargyrum cum cretâ, I believe it must have done so *post*, or in spite of the remedy.

I now come to a much more vexed question. Dr. Griffith says, "Is the bichloride of mercury wholly inert in thickened and indurated condition of the cervix uteri?" Now, if there is any one point on which mercurialists insist more than another, it is upon the solvent power of the bichloride of mercury upon indurations, whether of the cervix uteri or other part. I can only reply to Dr. Griffith's question by stating, that everyone who has watched cases of induration of the cervix uteri must recognise how unamenable they often are to any *constitutional* treatment; and I have seen that condition subsist under doses of mercury continued for a lengthened period, and which, in my opinion, had greatly deteriorated the patient's general health. As to indurations on the penis, we all know that they may be seen years after a mercurial course. It therefore appears to me to be a most ill-judged practice to ingest a destructive drug for weeks or months into the system, in order to try experiments upon the solution of an indurated mass. Why not use it in the induration of cancer? Simply because that practice has gone out of belief, since the pathology of the disease has been studied.

Dr. Adams, in his translation of Hippocrates, justly observes, with regard to the treatment of inflammation by calomel and opium: "The experience of some thirty years would seem to decide in its favour; but how often have certain methods of treatment in other cases obtained the sanction of professional favour for a much longer period, and yet, in the long run, been abandoned as positively injurious. In my young days, I knew physicians of the very highest reputations, who administered these medicines in scrofula, in cancer, in every case. We cannot think of the change of professional opinions on the mercurial treatment of syphilis, since the days of Hunter, without the most painful feelings of mistrust in all modes of treatment; where we cannot recognise some reasonable bond of connection between the remedy applied and the effects produced; or where long experience and analogy are in favour of them; and where the judgment runs no risk of being imposed upon by fallacious appearances and collateral circumstances."

Dr. Sisson, in the MEDICAL CIRCULAR of April 27, has also honoured me by some most useful criticisms upon the evidence I have adduced to prove that mercury causes disease, instead of being a remedy. He says: "I maintain that Dr. Drysdale's own authorities negative the idea that mercury can be dispensed with in the treatment of syphilis. To elicit truth is the object aimed at; and therefore it is not allowable to support a theory by an exaggeration of facts, or a *suppressio veri*. I must, therefore, complain that Dr. Drysdale is free from neither of these faults. Authorities, where denunciations are levelled against the abuse of mercury, have been cited in a manner to lead to an inference wholly opposed to their practice. Mr. Syme has been quoted in this way; but Mr. Syme gives mercury in syphilis, and calls mercury the grand remedy for iritis, given so as to affect the system. See 'Principles of Surgery.'"

When the body of the profession shall consent to treat syphilis in the manner recommended by Mr. Syme, I, for one, shall have nothing further to say. My attacks are levelled against those who treat syphilis by the ingestion, for several months, of a daily dose of this most dangerous drug. M. Ricord and his school, at present a dominant one both in Paris and London, recommend six months of a daily dose of iodide of mercury, followed by three of iodide of potassium. Let us hear what Mr. Syme says of this practice: "A fearful system of scientific quackery has, in recent times, been founded on the ruins of the old mercurial delusion; and although the so-called modified use of mercury, which is, at present, so much the fashion at Paris and elsewhere, may not be so speedy in its effects, I can testify, from what has frequently fallen under my observation, that it empties the pocket and injures the health no less effectually than the process of poisoning which it professes so advantageously to have replaced."

With the *mild mercurial school* it is difficult to come to terms. They do not assert anything categorically, but merely state, in general terms, that mercury does good in syphilis. To which all I can reply is, that I do not think it

ever does any good; but I also do not think that a few mercurial pills, given for a week or so, are worth speaking about, either for or against. As to Mr. Syme's recommending salivation in iritis, I believe that Dr. Sisson will find that I have never mentioned that gentleman in connection with that affection, but have referred to the evidence of Dr. Williams of Boston, Hugh Carmichael of Dublin, Dr. Hughes Bennett, and Mr. J. L. Laurence, to prove that mercury does harm, not good, in iritis.

Dr. Sisson goes on to say: "Dr. Drysdale has quoted from Dr. Grave's ClinicalMedicine, the—so-called—simple treatment of syphilis by Dr. Fricke in the Hamburg Hospital; and from the same work I extract the following passage. Fricke says: "Corrosive sublimate baths (℥j. to each bath) were often employed, and were of great service, &c., and seemed to remove the eruptions more speedily than even the nitric acid baths."

Dr. Sisson must surely recognise the distinction between the mere topical application of lotions, or baths of nitric acid, sulphate of zinc, or corrosive sublimate, which act as topical irritants and astringents, and the constitutional effects of the drug, when rubbed in, inhaled, or swallowed. As he has quoted from Fricke, however, allow me, Sir, to do the same from his 'Annalen,' a work which all should read, if possible, in the original German, or if not, in Grave's 'Clin. Med.' vol. ii. "The treatment of syphilis," says Fricke, "in the Hamburg Hospital was divided into two epochs, the mercurial and the non-mercurial. The former period was, for males, 18½ months—from January 1824 to July 1825; and for females, 21 months—from January 1824 to October 1825. The non-mercurial period lasted, with males, 2 years and 5½ months; and with females, 2 years and 2 months."

"1st Period, with Mercury."

"On looking over the tables (contained in the work) a considerable difference will be seen between them and those of the second period, syphilis having exhibited itself in a much more malignant form in the first period. Nocturnal pains, caries of the nasal, palatine, and other bones, obstinate and extensive cutaneous eruptions, general lues, syphilitic cachexia, were among the most ordinary phenomena; while, in the second period, they were of rare occurrence, and only observed in those who had been subjected to long and injurious courses of mercury. . . . . No undue predilection for any particular form of mercury was shown. . . . With regard to the duration of treatment, a difference in favour of the non-mercurial plan is readily perceived. . . . With regard to the certainty of cure we are convinced by bitter experience that syphilis very often returned in the secondary form, after the most careful use of mercury, the most careful selection of the preparations, the strictest attention to diet, and all proper precautions. Of 573 patients treated during the first period, one-third were attacked with secondary symptoms; all of them were treated with mercury for the primaries.

"Second Period, without Mercury.

"Having discovered, contrary to expectation, that the disease was cured more rapidly in this way, and relapses much fewer and slighter, it was extended to all cases, with such modifications as experience suggested. At this time, February, 1828, after a trial of two years and a half, and the successful treatment of more than one thousand patients, the results of this treatment have proved so favourable, that there appears no reason for lightly abandoning it, or returning to the former plan of treatment. As already stated, patients are cured in a much shorter period than before, and leave the hospital with much healthier looks. . . . Syphilis seems, too, gradually to become more simple; at least, it never appears in the same malignant forms as before, when little or no mercury has been used."

Fricke continued this treatment, and we are informed that, up to the year 1841, he had treated in the same way 15,000 cases. The above quotation from Dr. Fricke will show clearly, I believe, that he has completely put to rout the believers in the absolute necessity of treating syphilis with mercury.

In conclusion, I beg to thank Dr. Griffith and Dr. Sisson for their determination to discover flaws in my evidence as to the injurious effects of the internal use of mercury in all diseases. Were all the members of our Profession as single-minded and candid as these gentlemen, we should ere long have the experiment (?) made in our lock hospitals which has been so carefully made in the Hamburg Hospital, and recently by Professor Boeck in Christiania, and Mr. Weeden Cooke in London, of treating ulcers and eruptions without mercury, on the principles which guide us in other diseases. I am, &c.,

39 Southampton row, W.C., CHARLES DRYSDALE.
May 4, 1864.

POOR-LAW MEDICAL REFORM ASSOCIATION.

To the Editor of the Medical Circular.

SIR,—I shall feel obliged for space to inform the Poor-law medical officers that in 'Knight's Advertiser' of the 16th inst. is the following:—"It is understood that the Committee (Select Committee on Poor Relief, England) have agreed to resolutions on several subjects on which they have taken evidence, viz., the distress in the metropolis in 1861; the continuance of the central authority; the power possessed by the Poor-law Board of issuing general orders; *Medical relief;* pauper education; religious rights of workhouse inmates; district auditors; power of Poor-law Board to dismiss officers; equalisation of rating; casual and houseless poor; classification in workhouses, and *superannuation of paid officers.* It now only remains for the Committee to settle the terms of their report to the House. Mr. Villiers, the chairman of the Committee, stated on the 5th inst., in reply to a question of Mr. Göschen, that he was led to believe that the report would be presented before long, and in time for legislation this session."

Since April 14th I have received the following subscriptions towards the funds of the Association:—E. Hall, Ulverstone, 10s.; C. Heaton, Leek, 3s. 6d.; R. Cooper, Leek, 3s. 6d.; R. Purnock, Leek, 3s. 6d.; F. Robinson, Cheadle, 5s.; E. C. Buckoll, Radford, 5s.; J. Westell, Cookham, 10s.; S. A. Plumb, Cookham, 10s.; T. Hewlett, Hendon, 1*l.* 1s.; H. Horsfall, Wakefield, 10s.; B. Kemp, Wakefield, 10s.; E. Walker, Wakefield, 10s.; G. Walker, Wakefield, 10s.; G. F. Wills, Chard, 5s.; R. Ransome, Cambridge, 10s.; R. F. Thompson, South Shields, 7s. 6d.; J. D. Hulme, Blaby, 5s.; R. W. P. Kerswill, St. Germains, 5s.; E. J. Worth, St. Germains, 5s.; J. Yeoman, Whitby, 10s.; W. N. Clarkson, Whitby, 5s. I am, &c.,

12 Royal Terrace, Weymouth, RICHARD GRIFFIN.
17th May, 1864.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 5 AND 19.

Mr. PRESCOTT HEWETT, PRESIDENT.

(Continued from page 331.)

Dr. OGLE showed a

FIBRINOUS PLUG OBLITERATING A PART OF THE MIDDLE CEREBRAL ARTERY, AND CAUSING A SOFTENING OF THE BRAIN IN THE NEIGHBOURHOOD.

The fibrinous plug was adherent to the arterial walls, and decolourised, and the softened brain below the surface was of a very soft consistence, extending as far inwards as the right corpus striatum. The heart and its valves were healthy, but adherent to the inner surface of the ascending aorta, at about one inch above the aortic valve, very large fibrinous deposits, the so-called "vegetation," were met with. Masses or wedges of fibrinous deposit were also found in the spleen and one kidney. The patient (an intemperate man, aged 34), who had been subject to epileptic seizures, was admitted into St. George's Hospital with pain in the right side of the head and right temple, and having a peculiar "heaviness" of manner; the left arm was very cold, and weaker than the right one; the muscles of the left side of the face were wanting in power and expression;

the left pupil was dilated; and shortly after admission he had an epileptic attack, in which the muscles of the left side of the body were much convulsed, and the mouth drawn to the right. Eventually, gangrene of the great toe, and afterwards of the dorsum of one foot, came on; and he sank and died one month after admission.

SECONDARY ABSCESS OF THE BRAIN FOLLOWING AMPUTATION.

The purulent accumulation was of about the size of a filbert, and situated on the lowest part of the middle lobe of the left cerebral hemisphere. The other parts of the brain were healthy. The patient, a man aged 35, had left the Hospital after an amputation of the forearm. Having been frequently drunk, he was again admitted, owing to shivering, sweating, and vomiting. The rigors recurred daily, at almost the same hour, reminding one of ague. An abscess formed in one of the buttocks, the general surface became very yellow, and he sank and died twenty-seven days after admission. After death, in addition to the cerebral abscess, a small part of the ulna was found necrosed, and a large abscess was found within one of the deltoid muscles.

EXTRAVASATION OF BLOOD INTO THE PONS VAROLII, AND ALSO, BUT TO A SLIGHTER DEGREE, INTO THE LEFT OPTIC THALAMUS AND RIGHT CORPUS STRIATUM.

The pons Varolii was much broken down, and the extravasation extended into the right crus cerebelli, and had broken into the fourth ventricle. Much bloody fluid existed in the lateral ventricles, whose septum was broken down. The patient, a man, aged 49, was admitted into St. George's Hospital quite sensible and coherent in conversation. He had staggered on walking home after having drank two glasses of beer, and complained of being unable to see properly. When examined, there was loss of power to move the legs, the skin of which was without sensation, and there was incontinence of urine. He vomited a quantity of stuff smelling strongly of beer. He became comatose, and died on the day after admission.

EXTRAVASATION OF BLOOD INTO THE CENTRAL PART OF THE PONS VAROLII, EXTENDING INTO BOTH CRUSA CEREBELLI.

The patient was a drunken woman, aged 33, who for some time had suffered from headaches and giddiness. She had been "hemiplegic" on the left side since a fit which occurred two weeks previously, and had never regained consciousness. When admitted the speech was inarticulate, and there was no sensation or power of moving the muscles on the left side of the body. Difficulty in breathing and swallowing came on; she became comatose, and died three days after admission. The heart, lungs, kidneys, &c., were found healthy after death.

PARAPLEGIA FROM SOFTENING OF THE SPINAL CORD ASSOCIATED WITH A LARGE CALCULUS IN THE BLADDER; PROBABLY, IN THE ONSET, AN INSTANCE OF "REFLEX PARAPLEGIA."

The case was that of a gentleman, about 58 years old, who had in early life suffered much from gravel and irritation of the kidneys. Twelve years before death he had begun to pass blood in the urine after a slight fall or slip down a bank. Subsequently, pus was passed by the bladder, with and without blood, in large quantities. About five years after the first symptoms, difficulty in walking and numbness of the legs came on, and gradually almost complete loss of power in the legs was established. A calculus was detected in the bladder by Mr. Adams, of Harrington square, but as it was surmised that disease of the kidneys existed also, any operation with a view to remove the calculus was not considered advisable. Eventually, and a few days before death, loss of sensibility of the skin of the legs and face was experienced, and hyperæsthesia of the arms came on. The patient died, owing to accumulation of mucus in the bronchial tubes. After death, the bladder, containing the calculus, weighing 2¾ oz. and 40 grains, was found very inflamed, and a large abscess in the left kidney was met with; there were also indications in the left ureter that a calculus had at some time been impacted therein. There was extensive softening of the lower part of the *lumbar* region of the spinal cord, and also of the lower part of the *cervical* region. Dr. Ogle thought that, in connexion with this case, the question as to the interference which the existence of paraplegia might be supposed to produce with operative measures for the relief of stone in the bladder, might fairly be raised, and it was mainly with a view to that general question that he had exhibited the specimen. In reference to this subject Dr. Brown Sequard had told Dr. Ogle that, judging from his experiments upon certain of the lower animals he should consider the presence of paraplegia rather an advantage than detrimental, in case that lithotomy had to be performed.

The PRESIDENT said that if, in a case of paraplegia with stone in the bladder, there was kidney disease, he should not operate; but that the fact that there was paraplegia would not deter him.

RUPTURE OF THE HEART.

This was presented to the Society for Mr. Roper, of Shoreditch; and the principal point of interest was, how far the surgeon and the public were justified in attributing the patient's death to starvation. The latter was a woman about 60 years of age, and was endeavouring to subsist on a few pence a-week in a lodging containing no fire, and having no clothes to cover her. She died suddenly and there was found a laceration through the left ventricle. The coronary artery was diseased, and the muscular tissue was pale and soft. There were sufficient morbid conditions found in the organ to account for the rupture; but at the same time Dr. Wilks thought that an impoverished condition of the blood might have aggravated the tendency to muscular degeneration, and that the remarks of Mr. Roper before the coroner were quite reasonable—"That the deceased died immediately from rupture of the heart; but that privations, want of nourishment, proper clothing, and of warmth, would undoubtedly have accelerated the rupture of the heart. There was no trace of fat in the interior of the body."

LARDACEOUS DISEASE OF THE VISCERA.

The liver, spleen, and kidneys of a young man were shown who had long suffered from this form of disease. The point of interest was in the fact that, on the surface of the liver, where it was adherent to the diaphragm, there was a layer of pnre lardaceous material almost an inch thick. In this no trace of hepatic structure was visible; and it thus seemed as if a free deposition of the adventitious material had taken place on the outside of the organ.

Mr. SPENCER WELLS exhibited three specimens of

CANCER OF THE OVARIES.

In the first case both ovaries were affected. The patient was married, forty-four years old, childless, and the disease had been of three years' duration, but had only caused much inconvenience during the last year of life. Six months before her death ten pints of fluid were removed by tapping. Mr. Wells only saw her six weeks before her death, and made the diagnosis of two ovarian tumours surrounded by ascitic fluid, and from the cadaverous aspect suspected malignancy. Fifteen pints of ascitic fluid were removed by tapping, and hard masses were then felt more distinctly in the abdomen and pelvis. She lived about five weeks after the tapping, and died exhausted. The tumours were distinctly cancerons, and the peritoneum was studded with cancerous tubercles. The second patient was also childless, though she had been married twice; she was fifty-nine years old. Only the left ovary was affected. The tumour had been surrounded by ascitic fluid, which had been removed several times by tapping. The disease was only about twelve months from its commencement to its termination. After death the tumour was found to be inseparable from the bladder, uterus, and rectum. Portions of it were distinctly cancerous. The third was a case of encephaloid in a girl between thirteen and fourteen years old. The growth had been extremely rapid, only having been noticed about two months before death. Microscopic sections, prepared by Dr. Wilson Fox, were exhibited to show that the stroma of the right ovary was infiltrated with cancer. But whether the mass of soft cancer which had filled the pelvis had originated in the ovary or had extended to it, Mr. Wells was doubtful. The question of ovariotomy had been considered in all these cases, but had been negatived by the visible cachexia indicative of malignant disease.

Mr. SPENCER WELLS also exhibited a specimen of

TUBERCLE OF THE OVARY.

The deposit was observed beneath the peritoneal coat of a large cyst which Mr. Wells had removed from a single lady, twenty-three years of age, who died five days after the operation from diffuse peritonitis of a low form, probably tubercular.

Dr. WILSON FOX described this cyst as single, with the exception of a few scattered thin-walled cysts on the inner surface. On the outer surface, beneath the peritoneal coat, and firmly blended with the surrounding stroma of the cyst-wall, there were numerous nodules about the size of peppercorns, of a cartilaginous hardness, appearing on section glistening and semi-transparent at the circumference, and opaque and cheesy at the centre, which was slightly softened. The nodules themselves were without any trace of vessels, but the tissue around each nodule was very highly injected, and in the injected area there were delicate false membranes studded with the finest granulations of miliary tubercle. False membranes were also seen on other parts of the tumour containing fine granulations of miliary tubercle; and similar grey granulations, not larger than a pin-point or a poppy-seed, were seen on other parts of the outer wall of the cyst. Under the microscope, the outer part of the larger masses and small grey granulations were seen to have the same structure, and to consist of slightly elongated cells containing large, round, very clear, highly-refracting nuclei, each nucleus containing a nucleolus. The nuclei were in some parts free. In some parts of the field, cells with two nuclei could be seen; these were embedded in a clear, separating, finely striated, and very firm intercellular substance. The cells averaged 1-25000th in diameter, the nuclei 1-45000th. The cheesy yellow matter in the centre of the nodules consisted of oil globules, granular *débris*, and shrivelled cells. From these characters Dr. Fox had no doubt that the nodules and grey granulations were of tubercular nature.

In reply to Dr. BRISTOW, Mr. WELLS said that no post-mortem examination had been allowed, so that he could give no information as to the state of other organs; but the lungs had been examined during life, and were believed to be healthy.

Mr SPENCER WELLS then exhibited the uterus, left ovary, and pedicle left after removal of a tumour of the right ovary, the patient having died three days after.

RETURN OF THE LIGATURE INTO THE ABDOMEN.

About two pints of dark red serum had been effused into the peritoneal cavity, which contained neither blood nor ovarian fluid. The recent lymph was confined entirely to the lower and back part of the abdomen and pelvis, the peritonitis radiating from the pedicle, not from the wound in the abdominal wall, which was completely united, nor from a surface where the cyst had been adherent. There was no such attempt to capsulate the pedicle and ligature as there probably would have been had the patient been in better health. She was a married, childless woman, fifty years of age. Mr. Wells thought her chances of recovery would have been greater had it been possible to keep the end of the pedicle outside the abdomen, and he stated that the trials which he had made of returning the pedicle seemed to teach that in young or healthy subjects where circumscribed peritonitis and effusion of plastic lymph might be expected the practice was a good one; but in debilitated or cachectic patients, in whom diffuse peritonitis and effusion of serum, or of aplastic lymph might be feared, it would be safer (when the clamp could not be used) to leave the ends of the ligatures hanging out through the wound, and thus secure an opening for the escape of effused serum, and for the ligature itself with the tissues enclosed in it after their separation.

WHITE SWELLINGS.—Dr. Pécholier speaks highly of the good effects of Scott's apparatus in white swellings. He relates a case in which articular disease of two years' standing was entirely cured in the space of eight months.—'Journal of Practical Medicine and Surgery.'

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the College of Examiners on the 10th inst.:—Henri Victor Bertin, L.R.C.P.Lond., St. John's wood; Charles Claridge Brewer, Newport, Monmouthshire; Henry Todd Broughton, Bradford, Yorkshire; Edwin Burrell, Westley, near Bury St. Edmunds; George Alex. A. Coates, Sirhowy, Monmouthshire; J. Saltus Conyers, Demerara, West Indies; John Drust, Gainsborough; Robt. Charles Earle, Totnes, Devon; William Richard Goodfellow, Commercial road; George Grewcock, Folkingham, Lincolnshire; Charles St. Aubyn Hawken, Redruth; T. Edward Darley Hayes, Liverpool; Frederick Henry Hume, Angel terrace, Islington; Henry Gilbert Jackson, Leeds; Charles Frederick Knight, L.S.A., Brill, Bucks; William Slingsby Mann, Birmingham; Herbert Charles Pickard Masser, Langford, near Coventry; Joseph Morris, L.R.C.P. Lond., and L.S.A., Stupley, Warwickshire; George Paddon, Hitchen, Herts; Henry Richard Smith, Newark, Notts; Herbert Branwhite Spurgin, Thrapston, Northamptonshire; Jesse Wheelock Thibou, Antigua, West Indies; Martindale Cowslade Ward, Markham square, Chelsea.

The following were admitted Members on the 11th inst.:—Robert Francis Allen, Cloughjordan, Co. Tipperary; Joseph William Barrett, Eton; Ralph Alexander Busby, Leamington; John Thomas Caldwell, L.S.A., Knutsford, Cheshire; James Bunter Colthurst, Bristol; Eugene Fran. Cronin, M.D., St. Andrew's, Clapham; William Astly Sherratt Dykes, L.S.A., Hull; John A. Eatock, Rivington, near Bolton; William Henry Flint, Buxton, Derbyshire; Charles William Ellis Foster, Aldershot; Peter Harding, Shrewsbury; James Hamilton Martin, Tregony, Cornwall; Frederick Le Fevre Milburn, Leiston, Saxmundham; A. Miller, Highbury; Charles Fox Oxley, Pontefract, Yorkshire; Albert Louis Peacock, L.S.A., Huntingdon; Wm. A. Rudd, Hull; Walter Smith, Bognor, Sussex; William A. Sparling, Norwich; John Williams, Anglesey; Samuel Henry Woodgates, M.D., University Glasgow, Hereford.

At the same meeting of the Court, Mr. William Anderson, of the Royal Marine Artillery, passed his examination for Naval Surgeon. This gentleman had previously been admitted a Member of the Edinburgh College of Surgeons, his diploma bearing date July 17th, 1855.

In our Pass List last week, under the above head, for "C. L. Ridant," read "Charles Lyon Ridout."

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 12th inst.:—John Henry Ashton, 10 Upper Barnsbury street; Robert Chapman Gibson, Fyfield, Ongar, Essex; William Jones, Trewalter, Brecon; William Coleridge Kiernander, 2 Brunswick square; William Norris Marshall, Upper Northgate street, Chester.

The following gentlemen also on the same day passed their first examination:—Henry Hargreaves Birtwell, St. Thomas's Hospital; Edward Monroe Spooner, London Hospital.

UNIVERSITY OF CAMBRIDGE.—The examination for the degree of Master in Surgery was to take place on the 24th of this month, instead of on the 30th as before announced.

ST. BARTHOLOMEW'S HOSPITAL.—The Bentley Prize for the best report of medical cases occurring in the wards during the previous year has been awarded to Mr. William Vawdrey Lush, M.R.C.S.E. A Scholarship in Medicine, Surgery, and Midwifery has also been awarded to the same gentleman.

DR. ROWE.—We are glad to learn that this gentleman had sufficiently recovered to appear at the police-court, Liverpool, to give evidence against Brice and Scott for the assault committed by them on the 2nd of April. The prisoners were fully committed for trial, bail being refused.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—DISTRIBUTION OF PRIZES.—On Thursday, the 12th inst., the prizes

in the several classes of the Westminster Hospital Medical School were distributed to the successful competitors by the Very Rev. the Dean of Westminster, who was supported on the occasion by the Rev. Canon Nepean, Mr. Anderdon, one of the Vice-Presidents of the Hospital, Mr. Bedford, Mr. Furnivall, and the Medical Staff and Lecturers, besides numerous friends of the pupils. Mr. Power, the Dean of the School, opened the proceedings by reading his annual report of the Medical School, in which he gave a most favourable account of its condition and of the diligence and conduct of the students, and particularly adverted to the success with which all the pupils had passed their several examinations during the past season. The following prizes were then distributed by the Very Rev. the Dean of Westminster:—*Summer Session*, 1863.—Practical Chemistry, Mr. G. P. Bate—prize, surgical instruments; Materia Medica, Mr. G. P. Bate—prize, surgical instruments, and Mr. R. Bugden—certificate; Botany, Mr. R. Bugden—certificate; Forensic Medicine, Mr. George E. L. Pearse—certificate; Midwifery, Mr. G. P. Bate—prize, surgical instruments, Mr. George E. L. Pearse—certificate, and Mr. Ralph Burnham—certificate. *Winter Session*, 1863-64.—Anatomy, Mr. G. P. Bate—prize, surgical instruments, Mr. R. Bugden—certificate, Mr. Brooks—deserving of honourable mention, and Mr. W. Moore, ditto; Chemistry, Mr. J. C. F. McDonald—prize, Scott's Poems and Tennyson's Poems, Mr. W. Moore—certificate, and Mr. Wm. C. Watson—certificate; Physiology, Mr. G. P. Bate—prize, surgical instruments, and Mr. J. C. F. McDonald—certificate; Medicine, Mr. Wm. Yates—prize, Bible, and Mr. G. E. L. Pearse—prize, Scott's Poems (*æq.*); Surgery, Mr. Ralph Burnham—prize, Staunton's Shakespeare and Longfellow's Poems, Mr. G. E. L. Pearse—certificate, and Mr. C. St. Aubyn Hawken—hon. mention; Clinical Medicine, Mr. G. E. L. Pearse—certificate; Clinical Surgery, Mr. C. St. Aubyn Hawken—certificate; Dental Surgery, Mr. G. P. Bate—prize, dental instruments, and Mr. Oakman—certificate; Chadwick Prize, Mr. G. E. L. Pearse—Lowe's Ferns, Tennyson's Poems, and surgical instruments; Prosector's Prizes, Mr. C. St. Aubyn Hawken and Mr. Ralph Burnham. Dr. Basham made some remarks upon the Chadwick Prize, which he said had been founded in perpetuity by a lady who had been a most munificent benefactor to the Westminster Hospital in memory of her husband. He also spoke in the highest terms of the gentleman who had gained the prize this year (Mr. Pearse), who, he said, might be considered in all senses a Westminster student, since he was the son of an old Westminster Hospital pupil, and had received his general education at the Westminster School, which preliminary education Dr. Basham thought had had considerable influence upon his subsequent success. Mr. Barnard Holt proposed a vote of thanks to the Dean of Westminster for his kindness in presiding on the occasion. The Dean, in returning thanks, said that it had given him great pleasure to preside, and that there were only two drawbacks to his efficiency on such an occasion—namely, that he did not profess either a knowledge of science or great readiness of speech. He had always taken great interest in education and in the rising generation, and it was, therefore a sincere pleasure to him to see so many gentlemen making such satisfactory progress in their studies. He had lately been speaking respecting hospitals to a distinguished man of letters, who had said that what struck him most with regard to modern hospitals was, that a hospital for the sick and a school of instruction for students could be satisfactorily united, seeing the great difficulty there always was in uniting any two interests. He thought that the Medical Profession was the only one in which it was impossible to rise but by hard work and personal qualities, for in diplomacy, in the law, and even in the Church, a man might be pushed on by interest and personal connection. Hippocrates had said, "Art is long and life short;" life was still short, but art, and medical art particularly, had become enormously extended by the discovery and addition of new sciences; and he therefore exhorted the student not to cease in his efforts to obtain knowledge when his actual days of studentship were passed.

VICHY WATER.—'La Semaine,' of Vichy, states that 1,460,000 bottles of the mineral water were exported in the course of the year 1863.—'Journal of Practical Medicine and Surgery.'

THE VENOM OF REPTILES.—In a paper on the Venom of Reptiles, Dr. Desmartis, of Bordeaux, remarks that the action of venoms is very far from being the same. Thus, Cleopatra's aspic causes apoplexy; the poison of the horned viper, spasms; that of the dipsas, sore-throat, with excessive thirst; that of the viper, jaundice; the bite of the lætaen of Arabia, general tumefaction of the body; and those of other kinds of serpents, lockjaw or mortification. The author observes that these various effects might be taken advantage of in medicine; and he inquires whether, by judicious inoculation in given cases, good effects might not possibly be obtained from the peculiar action of each poison.—*Ibid.*

NEW WORK BY M. FLOURENS.—M. Flourens has just added one more volume to the numerous publications in which he has brought the light of philosophical inquiry to bear on the most obscure questions of natural history. His present work is an extremely lucid critical essay, on Mr. Darwin's celebrated treatise on the 'Origin of Man.' M. Flourens cannot agree with Lamarck, Geoffroy, Saint Hilaire, or Mr. Darwin, and ascribes the popularity of their opinions to their very strangeness. Lamarck, for instance, traces back to the polypus the origin of man, and Mr. Darwin assumes that all the different animal genera are constantly undergoing a process of successive transmutations.—*Ibid.*

An interesting discussion, which took place two years since, on the subject of hospital hygiene, at the Académie de Médecine, originated in a visit made by M. Le Fort to the hospitals in England. This gentleman established a comparison which proved most unfavourable to French Nosocomial Institutions, and although his remarks awakened impatient contradiction at the time, their correctness is now so fully admitted on all hands, that M. Lé Fort has been entrusted with the mission of visiting the principal hospitals in Europe, more especially those of Germany and Russia. This choice is doubtless most flattering to M. Le Fort, but also speaks highly in favour of the sense of equity of the Director of Public Assistance.—*Ibid.*

DEATHS.

BROWNE.—On the 9th inst., at Kiltigan, Baltinglass, R. Browne, L.R.C.S.I., Surg.-Major 25th Regiment.

HOWELL.—On the 8th inst., T. Howell, M.R.C.S.E., of the New Kent road, aged 49.

JOCE.—On the 4th inst., John Joce, M.R.C.S.E., o Colchester, Essex, aged 58.

JOHNS.—On the 11th inst., at Lower Fitzwilliam st eet, D lin, Robert Johns, M.B., F.R.C.S.I., aged 49.

RIACH.—On the 14th inst., at Allanbank, near Perth, Riach, M.D., formerly Surgeon 67th Foot, aged 73.

SKINNER.—On the 13th inst., at Sandyford place, Glasgow, H. T. Skinner, M.D.

TAYLOR.—On the 13th inst., at the New Passage, Gloucestershire, J. Taylor, Surgeon R.N., aged 75.

WELLS.—On the 15th inst., A. Wells, M.R.C.S.E., of Basingstoke, Hants.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, MAY 25.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, MAY 26.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; Great Northern Hospital, King's cross, 2 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopœdic Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Hullah "On Music (1600—1750)."

FRIDAY, MAY 27.—*Operations* at Westminster Ophtha Hospital, 1½ p.m.; Royal Institution, 8 p.m.—Mr. Re S. Poole, "On Greek Art."

SATURDAY, MAY 28.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital,

1½ p.m.; King's College Hospital, 1¼ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Alexander Herschel, "On Falling Stars and Meteorolites."

MONDAY, MAY 30.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, MAY 31.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

A Handbook of Uterine Therapeutics. By Edward John Tilt, Esq., M.D. Second edition. London: John Churchill and Sons.

Lectures on Epilepsy, Pain, and Paralysis. By C. B. Radcliffe, M.D. London: John Churchill and Sons.

Lectures on Diseases of Women. By C. West, M.D. Third edition. London: John Churchill and Sons.

Practical and Pathological Researches on the Various Forms of Paralysis. By E. Meryon, M.D. London: John Churchill and Sons.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

QUÆSO.—In answer to a correspondent who addressed us under the above title, a notice appeared in our last number on page 341, which notice, having been inadvertently inserted without being submitted to the supervision of the Editor, contains one or two errors which altogether alter its meaning. The notice should read as follows:

QUÆSO.—In paralysis death from congestive pneumonia is not infrequent. In partial paralysis at the junction of the healthy and diseased parts the sensibility is most exquisite, owing to the fact that, while compression by means of the depressed bone exists in one part and occasions want of motion and feeling, another part of the cord or a nerve running from it is not compressed but irritated, and the pain is usually referred, not to the part directly acted upon, but to the extremity of the nerve or nerves communicating with that part. Fractures in the lumbar region running into the sacral will be attended with paralysis from the knee downwards; occurring, however, in the dorsal, the paralysis will involve the whole of the lower extremity.

MR. F. J. WILSON.—The report has been received and is inserted.

DR. GASON, *Rome*.—The paper has been received, and will be published next week.

MR. RICHARD GRIFFIN.—The letter is inserted.

DR. SISSON'S paper has been received.

MR. J. L.—The card arrived too late to be available for the purpose specified.

MESSRS. W., *Chelsea*.—The letter reached us, but not the diagrams which are described as accompanying it.

A RURAL SURGEON.—The best work on the subject of Embolism is a voluminous one by a German author named Cohn. It may be obtained of any of the foreign booksellers.

DR. H.—The announcement will be too late for our next number.

YOUNG CHEMIST.—There is no relationship except an etymological one between lithia and lithic acid. It would be better to call the latter always by its synonym "uric acid."

To the Editor of the Medical Circular.

SIR,—Would you kindly inform me when the preliminary examination of the Royal College of Surgeons in England is held, and whether, by passing that, I should be exempted from the examination in arts of the Society of Apothecaries? If you would insert an answer in your paper, you would greatly oblige, Yours truly, A CANDIDATE.

Belper, May 21, 1864.

[1. The time may be learned by application to the Secretary of the College. 2. Yes.—EDITOR OF MED. CIRCULAR.]

Royal College of Physicians of LONDON.

FIRST Part of the PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination of Students who have completed their Second Winter Session of Study at a recognised Medical School will commence on Tuesday, June 7th.

SECOND PART of the PROFESSIONAL EXAMINATION.—An Examination of Gentlemen who are eligible for admission to the Second Examination for the Licence will commence on Tuesday, June 14th.

Registered Medical Practitioners qualified before January, 1861, are admitted to Examination under special Bye-law.

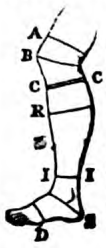
Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

H. A. PITMAN, M.D., Registrar, Pallmall East.

Anatomy, Physiology, Pathology, and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland Place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.



The Medical Baths and Fumigations. 40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour. Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Baréges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic sease where internal medicines are inadmissible, or have altogether failed effect. Imitations having arisen, be particular in the address.

FOR VARICOSE VEINS AND WEAKNESS.

SURGICAL ELASTIC STOCKINGS AND KNEE-CAPS,

Pervious, light in texture, and inexpensive, yielding a permanent and efficient support under any temperature, without the trouble of Lacing or Bandaging; likewise a strong, low-priced article for Hospitals and the Working Classes.

ABDOMINAL SUPPORTING BELTS.

Those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with EXTREME LIGHTNESS—a point hitherto little attended to. Instructions for measurement, and prices, on application, and the articles sent by post, from the Manufacturers,

POPE AND PLANTE,

Superior seamless Cotton Bandage Manufacturers,

4 WATERLOO PLACE, PALLMALL, LONDON.

The Profession, Trade, and Hospitals supplied.

DINNEFORD'S

Pure Fluid Magnesia, now perfect in purity and strength.

"Mr. Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.,) specially adapted for the use of Medical Men and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

Weiss's Illustrated Catalogue, containing nearly 800 Engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price 5s.

62 Strand, London.

"This Catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced; and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour, which we are glad to see strictly observed in this Catalogue."—Vide 'TheLancet,' Sept 12th, 1863.

Labels Cut by Machinery.—Adhesive for marking goods, 1s. per 1,000; Dispensing or Chemical, 2d. per 100, kept in stock; with Name and Address, 2s. per 1,000; Mixture, Pill, &c., equally moderate. An assortment of Labels for all trades. Contracts with large consumers.

J. CROSS, & SON, Engravers, Steam Machine Printers, Lithographers, and Stationers, 18 Holborn Hill, E.C. Established 1813.

A Cup of Coffee in One Minute. —DUNN'S ESSENCE of COFFEE, 1s. and 2s. pe bottle. May be had everywhere. Warranted to keep good in any climate.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ACCOUNT OF A SHORT TOUR IN SWITZERLAND, MADE DURING THE MONTHS OF AUGUST AND SEPTEMBER, 1863; TOGETHER WITH A SKETCH OF SOME OF THE HOSPITALS, &c., VISITED IN THAT EXCURSION.

By JOHN GASON, M.D., Fell. Coll. Phys. Ireland, &c.

A medical man's holiday may be not only of great benefit to his physical system, but also a source of practical instruction to his own mind, and by the communication of the information which he may have gathered be also a benefit to others. Though the amount of instruction gathered at such times is frequently so slight as not to be considered worth the trouble of transcribing it, yet, if done in every instance, a large amount of useful information might be collected, and a general and practical benefit be conferred.

During the last summer, I availed myself of two months' tour in Switzerland to visit, in every town which I passed through, most of the hospitals and public institutions. A short sketch of these institutions it is my intention now to give, hoping on some other occasion to make myself more intimately acquainted with those from the inspection of which I derived much pleasure. On passing through Milan, where I spent three days, I visited the hospital named "Ospidale Maggiore." To give much information from two visits to such a large building would be quite impossible, but what I do state may be depended on for its accuracy. This hospital is richly endowed. It contains about 3,000 beds; 2,900 were occupied on my two visits. On entering there is a fine open quadrangle. To the front are the various offices connected with the institution. Medical and surgical cases of both sexes are admitted. There are wards for diseases of children, as well as separate wards for diseases of the eyes. There are also wards for lunatics of both sexes. The female lunatic wards communicate with the children's wards—a curious arrangement! Lunatics, if violent, are strapped by the hands and feet to the bed. Religious madness of a violent nature is very common. Typhus and typhoid fevers prevailed at the time I visited it, to a great extent. These cases are allowed to remain in the same wards with persons labouring under other diseases.

A decided differencc is recognised between typhus and typhoid fevers, but the same treatment is adopted in both —namely, lemonade and cream of tartar drinks. Medicine is considered of but little avail in these fevers. When constant raving takes places, leeches are applied to the temples or behind the ears, which is said to relieve the symptoms. The treatment consists in watching the symptoms and treating them. Miliary eruptions often take place in these fevers. In one case of typhus fever which I saw, this eruption had appeared the day previously; the whole anterior surface of the chest was covered with small, clear, transparent vesicles. The patient was dying; nothing was done more than giving him drinks of imperial. Great attention was paid to his cleanliness, and he was kept dry, as his secretions were passed involuntarily. In another case of typhus fever, in which the patient lay in a comatose state, leeches had been applied to the temples; the blood was flowing freely from the leech-bites. The disease which he was labouring under when admitted was marked over his bed as intermittent fever. On the first day, he had shivering, heat, and perspiration, but from that time the fever was continuous. As this patient had attempted to get out of his bed, he was strapped to it by the hands and feet. The treatment, in addition to the leeching, was imperial drink.

There were a great many cases of gastric fever in the hospital, the usual symptoms of which consisted in quick pulse, hot skin, red lips and gums, white tongue, a deranged state of the bowels, and loss of appetite. These cases were generally cured in a week, by means of a dose of castor-oil, imperial drink, and light diet. The deaths in the hospital varied from ten to fifteen daily. After death the body is left in the bed for three hours, then removed to a small dead-room, adjoining the general dead-room. A bell-rope is attached to the wrist of each body, in order that, in the event of only apparent death, the least movement might ring the bell.

It is left in the small dead-room for three hours, from which it is removed to the general dead-room, where it is left for thirty-six hours previous to being removed for burial. Coffins are only used when paid for by the friends of the deceased; the other bodies are removed at the expense of the institution, and buried naked. My first visit to the hospital was in the afternoon: though the air of the wards was close, still there was nothing worse than what is generally perceived in Italian hospitals where the ventilation is not good; but when I returned the next morning, at eight o'clock, the stench was overpowering. Sufficient time had not elapsed to clear off the collected exhalations from 400 patients shut up in one ward. They were crowded together, barely thirty inches between the beds. Those adjoining the doors and windows (which were on a level with them) complained of the cold and wind, while those towards the end of the ward had the benefit of the concentrated mixture of bad odours driven in on them. A large proportion of the occupants of the beds were old people, suffering under chronic bronchitis. In fact, the hospital appeared more like a huge poor-house than an institution for the cure of disease. The kitchen was the only clean part of the house. The meat and broths appeared of the best quality, and in this respect the money was laid out with no niggardly hand. It would not require any prophetic vision to foresee the ravages that any severe epidemic would make in such an establishment, and still to those living in the hospital everything appeared perfect. It is said that great reforms were made in it by the French during the late war of independence in Italy. If so, *misericordia*. The most prevalent diseases in Milan during the winter are inflammatory affections of the chest, in which the lancet is considered the sheet-anchor. The city of Milan is very healthy; the majority of the cases which fill the hospitals come in from the country.

On crossing the Splügen into Switzerland, I observed a great quantity of the lichen called "Lichen Islandicus" was collected on the summit of that pass. The gathering of it forms a considerable source of gain to the poor in those parts. Twelve large sacks were ready for exportation to Italy.

The next hospital which I visited was that of Coire, the capital of the Canton of the Grisons. This town is about twenty-five miles from the Splügen; it lies in a plain, surrounded by mountains. The river Plessure runs through it, and empties itself into the Rhine, which flows at a short distance from the town. The soil is gravelly and the drainage good. The town is lighted with gas. The population is about six thousand. The air is dry and bracing. The diseases which prevail most in this locality are rheumatic affections, pleuropneumonia, affections of the heart, and of the mucous membrane of the chest and bowels. Typhus fever occurs frequently; typhoid fevers occasionally, in spring and autumn. Cancer is very common. Goitre is often met with, but not so frequently as in other parts of Switzerland. In the town of Coire, tubercular phthisis is seldom met with; in the country it occurs frequently. Hæmorrhage from the lungs is very seldom witnessed. Few persons pass ninety years of age. The climate is cold. The principal hospital belongs to the Capuchin monks; it is attended by Sisters of Charity. Persons of all religions, applying for admission, are received gratis. There are, however, paid beds, which any patient that will pay for can have. The hospital is under the sole direction of Dr.

Hammi, who attends both the medical and surgical cases. It contains forty beds. There are several small wards, with one bed in each. The wards are very close, and have no means of ventilation, except the windows, which are made in the same manner as those of any other house. It appears to me to have been built in such a manner, that, if it does not succeed in its object, it may be converted into a dwelling house. When the wards are closed at night, there must be a great want of pure air. In a small room, containing a single bed, was a case of typhus fever, complicated with congestion of the mucous membrane of both lungs. The treatment consisted in the internal exhibition of Kermes mineral, with camphor and decoction of senega. The symptoms did not appear of a serious nature. The windows and doors of this ward were kept closely shut. Typhus and typhoid fevers were not considered infectious by the medical men. This hospital was built in 1853 ; it is kept very clean and neat. About fifty yards from the hospital is a small house, containing a room for post-mortem examinations, and, attached to it, one for a pathological museum, which contains, however, but a few preparations. There is also another hospital in the town ; it is a dirty, wretched building. Too little cannot be said about it.

The next place that I visited was Ragaz, and the Baths of Pfafers, about one hour's drive by rail from Coire. These baths have acquired a certain amount of reputation for the supposed efficacy of the waters. The Baths of Pfafers are three miles distant from the town of Ragaz, and are connected with the latter place by an excellent carriage road cut through a wild gorge through which the river Tamina wildly dashes. Perpendicular rocks rise to an immense height on one side, and high wooded hills enclose this romantic ravine on the other. The bathing establishment consists of a large hotel, in which baths are fitted up for the accommodation of the visitors.

The source of the waters is close at hand; the temperature about 100 deg. Fah. The waters are clear as crystal and have no taste or smell. They leave no deposit. They are used for bathing purposes as well as for drinking, and are conveyed by means of wooden pipes to the town of Rauz, a distance of three miles, losing but 4½ deg. Fah. of their heat in their passage. These waters are found useful in affections of the stomach and bowels, as well as in diseases of the nervous system, rheumatism, scrofulous affections, diseases of the kidneys, arising from irritation or inflammation of these organs, and in diseases of the bladder, &c.

Numbers of females of a certain age, and others with scorbutic affections of the skin, were devoutly engaged in paying their devotions to the Water God. Amongst the male sex there were but few who had not passed the meridian of life, and to whom relaxation from business, freedom from anxiety, early rising, temperate habits, regular exercise, and plain, substantial food, with the absorption of a large quantity of warm water, thereby lessening their voracious appetites, must be beneficial. It is the practice to commence by drinking one tumbler of this water at a time before breakfast, and gradually increasing the number until eight or ten tumblers are taken in the course of the day. I witnessed one person drinking five tumblers of this hot water. The baths are used with much benefit, the time for remaining in them being gradually increased from fifteen minutes to one hour. The course consists of about twenty baths. The grounds connected with the establishment at Ragaz are laid out with taste for visitors, who flock here in great numbers; walks shaded by trees and lovely vistas meet you at every turn.

The hospital at Zurich, built about thirty years, possesses advantages like those of few hospitals that I have seen. It is built on the high grounds over the city, and is close to the Polytechnic. It is surrounded by an extensive enclosure, and is quite separated from any other building. The Typhus Fever Hospital is about 100 yards to the rear. The hospital contains about 300 beds. Both male and female patients are admitted. There are eye wards for both sexes. It is two stories in height. All the wards, with the exception of three or four, are to the front, from which there is an enlivening view—no slight advantage to patients recovering from illness. The wards open on a wide, well-flagged corridor, which is kept beautifully clean. The windows open down to within three feet of the floor. Each ward contains from ten to twelve beds. In the doors are openings both above and below, for the purpose of ventilation. There are water-closets out of each ward ; they are so contrived that no smell penetrates into the rooms. The means adopted for heating the hospital is steam, which is conveyed through all the rooms by means of leaden pipes. It appears ample for each ward. The ventilation, however, I believe, could have been effected in a better manner by means of large pipes carried above the roof from the ceiling of each ward, as is done and found so effectual in some of the cotton manufactories in England.

As a new hospital is likely to be soon erected in London, it would be well to take into consideration the plan of this excellent institution before any design is finally decided on.

Having visited the principal hospitals in England, Ireland, France, and Italy, I have no hesitation in saying that the new hospital at Zurich far exceeds in design, accommodation, and suitableness for such a purpose, all the others that I have seen. The lighting of the operation-room is particularly good. An operation for extirpation of the eye for malignant disease of that organ was ably performed by Professor Horner, the patient being under the influence of chloroform. Dr. Griesinger, one of the physicians, visited some of the wards; his manner of questioning the students on the diagnosis and treatment of the diseases of the patient was good ; and to any student anxious to learn, the opportunities afforded in that hospital are excellent. My recollections of the few hours which I passed there on two successive days are most pleasing.

The hospital at Lucerne possesses so few objects of interest that it does not merit a visit. It is clean, but the wards are small and close.

On my return on foot across the St. Gothard Pass, I visited the place where lay the bones of the French and Russian soldiers who fell on that pass, where 600 French resisted all the efforts of 3,000 Russians for twelve hours. Both parties deserved at least to be laid in a grave where nothing would disturb them until the last trump will sound their resurrection. The remains of the French and Russians were laid together, and a small chapel built over them. The chapel has been completely emptied of everything ; a hole was made in the roof by a sacrilegious attempt to erect a pole to support a telegraphic wire, and beneath, in a cleft between two rocks, lay heaps of whitened bones, washed by every shower of rain and exposed to public gaze as a lasting monument to the disgrace of those who, having used these heroes as instruments to their ambition, left their bones unburied to whiten amidst the snows—

> "A bony heap, through ages to remain ;
> Themselves their monument."

Judging from the length of the bones, which appeared of a larger size than is usually met with, I should say that those engaged in that fight must have been men of more than the usual stature.

I could not discover any appearance which indicated that the bones had been struck by balls, though many of them were fractured.

12 Via della Mercede, Rome,
May 5, 1864.

GRANT MEDICAL COLLEGE.—The annual exhibition for the distribution of prizes and scholarships to the successful students at the Grant Medical College, Bombay, was held on the 13th April. His Excellency Sir Bartle Frere presided on the occasion.

HONORARY DEGREES AT CAMBRIDGE.—Amongst the list of distinguished persons upon whom the honorary degree of Doctor of Laws by special grace will be conferred during the Royal visit, are the following names : Dr. Watson, President of the Royal College of Physicians ; Dr. A. W. Hofmann, and Professor Wheatstone.

HOSPITAL REPORTS.

WESTMINSTER HOSPITAL.

Some little time since, in our walk through the hospital, we saw a very interesting case under the care of Mr. Barnard Holt :—It was that of a little child (a male) who had recently suffered from rheumatic fever, and subsequently from abscesses in different parts of the body, the result, no doubt, of the generally deteriorated condition of the health, which in turn they tended to keep up and increase.

But the peculiarity of the case was this :—An abscess had formed in the lower extremity of the fore-arm and, pointing toward the ulnar side, had burst at a point corresponding to and a little above the styloid process of the ulna; the abscess discharged freely, making for itself a sufficiently large aperture of exit, and laying bare the bone for some distance. Through this opening the lower extremity of the bone worked its way as the child had used the fore-arm ; and upon the occasion of our visit some inches of the bone, which was dry and apparently deprived of all its vitality, were protruding through the aperture the abscess had created. As the condition of the child was very weakly, and it was not at all improbable that the entire ulna was diseased or already dead, Mr. Holt considered it advisable to leave altogether to Nature the processes which would ensue. The patient was very much worn and emaciated, and certainly possessed very little, if any, reparative power ; it was not, therefore, unlikely, if any interference were made with the bone, that inflammation of an unhealthy kind would be lighted up, destructive, perhaps, to the entire limb, should it not even prove fatal to life.

All these considerations being reviewed, Mr. Holt adopted the simple plan of treatment, that is, of giving the patient as much nutriment as could be digested, at the same time that the tone of the system was raised by the administration of cod-liver oil and of the iodide of iron, and the wound either poulticed (when such was indicated) or dressed with lint and simple ointment.

Another case of especial interest, because bearing upon a point contested strongly by some anti-mercurialists, presented itself in the wards :—The patient was a young girl who, some time previously, had contracted syphilis ; she stated that she had never taken any mercury, and on her admission into the hospital there was not any appearance of the drug having been administered. Certainly, her system had not been poisoned by the mineral, as some contend is the case when results occur similar to those which at present are observed. On the patient's speaking it was quite evident that there was something radically wrong with the palate, and we think that the cachectic appearance peculiar to syphilis could be detected : on opening the mouth the soft palate was found to be perforated just about its attachment to the palatal bones, in which there was likewise destructive disease ; the back of the pharynx presented the cicatrices of old specific ulcerations, and what was remaining of the uvula had become involved in these cicatrices, and was adherent to the pharynx posteriorly.

The patient most positively asserted she had been treated only on the simple plan, and there were no evidences of mercury having been administered, unless the conditions we have above mentioned be regarded as such, as they are by the opponents of this mineral.

Mr. Holt, in some remarks he made relative to the case under consideration, alluded to the different experience of different practitioners : one finding mercury his sheet-anchor in syphilis; another finding it wholly unnecessary to use this medicine in the particular disease—nay, more, viewing it as a poison rather than as a remedial agent. Such differences he considered it impossible to reconcile, unless each practitioner furnished the most accurate notes of his several cases, relative not only to the habit, circumstances, &c., of the patients, but also of the treatment pursued for the cure. Then, perhaps, a series of tabulated forms would show that much depended upon a difference in the phase of the disease, or in the character of the disease itself, in the condition or idiosyncrasy of the patient, in the preparation of the mineral, the time or mode of its administration, or in all these circumstances combined.

He mentioned a case in which the simple plan of treatment had been tried, and for some time, until it was unmistakable that the patient was growing worse ; the so-called specific method was then tried, to the immediate improvement of the sufferer and before the gums were touched.

Under the care of Mr. Holthouse, we saw a strong-looking, woman, suffering from granular lids of both eyes. From her general aspect it was apparent that the strumous diathesis was the latent source of the disease. The right eye was completely deprived of its power even of appreciating light: the conjunctiva covering it was thickened ; its vessels raised prominently above their wonted level, and ramifying over the cornea, which was opaque, and entirely hid from view by its thickened and chronically-inflamed conjunctival coat. The eye seemed to be nothing more than a disorganised mass, its only use being to maintain the lids in their usual situation, and to prevent foreign bodies entering the cavity of the orbit were it not occupied by the eyeball.

The treatment pursued was the employment of strengthening and anti-strumous remedies generally, and the touching of both upper and lower lids with the sulphate of copper—a plan of treatment that had of late years fallen into disuse in England, but, having been revived by the Vienna school of ophthalmists, has again been adopted in practice.

We would mention here, that in the Irish hospitals the sulphate of copper has maintained its reputation, and was not abandoned for any other local application, so much benefit had resulted from its use. Irish surgeons, therefore, deserve credit for *continuing* to use a remedial agent they knew from actual experience to be most valuable, and for persevering in its use when it was abandoned by the sister island.

The plan we have seen practised in the Dublin schools was first to scarify the lids with the lancet, dry them, and then rub them over several times with the sulphate. Under this treatment many were cured, and still very many more relieved. This form of ophthalmia is not by any means infrequent in Ireland ; it also prevails very largely in Egypt, China, India, and certain parts of Africa. In these countries it is originated by a combination of excessive and glaring light, produced partly by the direct rays of the sun and partly by those reflected from the sand ; also by particles of the fine sand being caught up into the air by the hot winds and blown into the eyes, by the hot winds themselves, and by the dirty habits of the natives. There is yet another cause, and which we do not know is mentioned by authors who have written upon this subject, but which is certainly, perhaps, the most frequent of any that could be cited : it is, the immense number of flies that fills the air in these tropical regions. Of this number, each fly becomes a centre of contagion by alighting upon the lids of the diseased persons, getting itself besmeared with the matter, and then again pitching upon the lids of another person, who may have been quite free from the disease till the virus was thus transmitted.

We have watched this process ourselves amongst the natives of the countries to which we have made reference: owing to the indolent, lazy, sluggish habits of the people, the flies, thus allowed to remain undisturbed upon the lids, may be seen sometimes depositing their ova in the gummy secretion which glues the lids together. In this manner, perhaps more than in any other way, is the disease propagated, till it spreads itself over an entire district, or becomes endemic.

Another case which we saw was one of extensive necrosis of the bones of the head, in a female patient. Mr. Holthouse had applied the trephine to one part of the calvarium, where he suspected the presence of some dead bone, but not finding any, though he had penetrated somewhat deeply, he discontinued the use of the instrument before the inner table was perforated. The cavity so made was afterwards stuffed with lint and cotton wool.

There was a profuse and fetid discharge from this and all the other openings, and which, no doubt, proceeded from the existence of dead bone, no matter how small it might be.

Near this last patient was a little child who had suffered from lupus or lupoid disease of the nose, but who had apparently become cured of the affection under the use of the liquor arsenicalis, cod-liver oil, and iodide of potassium.

In the Medical Ward, under the care of Dr. Fincham, we saw an interesting case of adherent pericardium, in which the diagnostic symptoms of the lesion were well marked: the sounds of the heart were propagated over a larger area than natural, and instead of the healthy beat or impulse, there was a peculiar irregular jogging motion; the heart, at times, striking forcibly against the walls of the chest, while at other times it would fail to do so, and seem suddenly to fall backwards. On the patient taking a deep inspiration, the lungs did not seem to be allowed to occupy the space which in health they should, on the performance of this act. No actual space ever exists, but as the lungs are filled with air, the walls of the thorax are expanded, and the lung, being extended in surface, passes in between the heart and the ribs; when it thus intervenes, the respiratory murmur is distinctly audible at the site of the heart, and the cardiac sounds are heard at a distance, that is, behind the intervening pneumonic murmur;—again, on altering the position of the patient, the heart did not change its situation, and this was at once conclusive evidence of its being bound down by firm adhesions.

The last case to which we shall advert is that of a woman who, very soon after her confinement, had become affected with ascites and an anasarcous condition of the lower extremeties, dependent, most probably, upon general debility; there was no renal disease, nor cardiac affection, nor had there been any difficulty attending her labour, nor any flooding subsequent to it: her labour had been in every respect good, and had been quick.

It occurred to our mind that this very quickness might have occasioned the present condition, owing to the too sudden removal of the pressure exercised by the impregnated womb upon the great vessels. The abdomen was enormously distended with flatus; this was accounted for by the fact of its having been so recently occupied by the enlarged uterus, which had relaxed its walls, and deprived them of the power of exercising control over the intestines, so that these latter, so lately pressed on from within by the gravid uterus, and from without by the abdominal walls, now left lying in the abdominal cavity, and ungoverned by any pressure, became distended with flatus, until they engaged the whole of that part of the abdomen unoccupied by the dropsical fluid.

The treatment consisted in the administration of the compound powder of jalap, so as to produce liquid evacuations, and of the tincture of the sesquichloride of iron.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—Erasmus Wilson, Esq., F.R.S., has been elected Senior Surgeon. Dr. Frodsham and Dr. Tilbury Fox have been elected Physicians.

ACTION OF FIRE ON A CORPSE.—When fire is applied to a living body a blister filled with liquid is soon raised, and if the heat be continued the epidermis is destroyed. But when the same heat is applied to a dead body the epidermis rises in the form of a blister, which is filled with vapour, and which presently bursts. This test has been proposed by M. Martin de Cordoux, to ascertain whether a person is really dead before the body is interred. In performing the test, the author recommends a small flame, such as the flame of a match, to be applied for a short time at about half a centimetre from the skin.

PATHOLOGICAL SPECIMENS FOR OXFORD.—In a convocation recently held at Oxford a grace was passed for the purchase of the pathological collection of 300 specimens formed by Professor Schroeder Van der Kolk at Utrecht. The cost will be 200*l*.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XVI.

PREPARED SULPHURET OF ANTIMONY.—This substance is described in Appendix A of the British Pharmacopœia. As it is the body from which all the officinal compounds of antimony are prepared, it will be convenient to notice it first.

Tersulphide of antimony is an abundant mineral, found in various parts of the world, but especially in Hungary, Borneo, and France. It occurs in the form of black crystalline masses, interspersed through a siliceous matrix, from which it is separated by simple fusion. The ore is either heated in a large pot provided with holes at the bottom for the fused sulphide to run out, or it is placed on the bed of a reverberatory furnace in which there is a passage for the fluid to flow off to the receiving vessel. Sulphide of antimony is met with in commerce in round cakes, which, when broken, present a highly crystalline fracture and almost metallic lustre. This crystalline sulphide, when reduced to fine powder, constitutes the prepared sulphuret of antimony of the British Pharmacopœia.

The black sulphide of antimony of commerce is never pure; it always contains iron, and frequently also arsenic, lead, copper, and siliceous matter. It it important, therefore, in preparing the compounds of antimony from this source, to adopt such processes as shall exclude these impurities. The Pharmacopœia directs that the sulphide shall be "almost entirely soluble in boiling hydrochloric acid." Sulphide of arsenic would to a great extent remain undissolved when thus treated, as would also the siliceous matter.

ANTIMONII TERCHLORIDI LIQUOR.—This preparation has been taken from the Dublin Pharmacopœia. Its principal use is in the production of oxide of antimony. This chloride is obtained by heating the prepared sulphuret with commercial hydrochloric acid. In the cold these bodies do not act on each other, but when warmed, abundance of sulphuretted hydrogen is liberated, and chloride of antimony is formed. The reaction which occurs may be thus expressed:—

$$Sb\,S_3 + 3\,H\,Cl = Sb\,Cl_3 + 3\,H\,S.$$

To get rid of the sulphuretted hydrogen, the Pharmacopœia directs the operation to be conducted beneath a flue with a good draught. When the evolution of gas has ceased, the liquid is to be boiled for fifteen minutes, the object of which is to expel all the sulphuretted hydrogen remaining dissolved in the liquid. The solution is then to be filtered through calico, and the clear liquid concentrated by boiling, so as to have the specific gravity of 1·47.

Several of the impurities of the sulphide of antimony remain undissolved by the hydrochloric acid, and are thus separated. The iron, however, which is always present, passes into solution and communicates a yellow or reddish colour to the liquid. Commercial butter of antimony is principally used in agricultural districts by the shepherds, who have a prejudice in favour of a very dark-coloured liquid; consequently, oxide of iron and a little nitric acid are frequently added by the manufacturer to the solution, in order still further to deepen its colour.

The liquor of the British Pharmacopœia consists of a concentrated solution of terchloride of antimony in hydrochloric acid, coloured by the presence of a little iron.

When this solution is submitted to distillation, the hydrochloric acid first passes over, and afterwards the chloride of antimony itself distils, and condenses into a solid mass of crystals. The solid terchloride, however, is most conveniently obtained by distilling a mixture of sulphide of antimony and bichloride of mercury; chloride of

antimony passes over, and bisulphide of mercury or "cinnabar of antimony") remains in the retort.

ANTIMONII OXIDUM.—The process given by the Pharmacopœia for the preparation of oxide of antimony is the one most generally employed, and is the best suited for the purpose. It consists in pouring the chloride of antimony into water, washing the precipitate so produced, then treating it with a solution of carbonate of soda, again washing and then drying. When the solution of terchloride of antimony, already described, is poured into water, a precipitate is formed consisting of oxychloride of antimony. When first formed, the precipitate is perfectly white and amorphous, but by standing for a little time in contact with the water it becomes crystalline, and in the latter condition has a definite composition. The change which occurs may be thus represented:—

$$6\,Sb\,Cl_3 + 15\,HO = (Sb\,Cl_3, 5\,Sb\,O_3) + 15\,H\,Cl$$

Oxychloride.

The impurities present in the chloride of antimony remain dissolved in the water and are removed in the washing; consequently, very pure oxychloride can be obtained from the crude liquid chloride. Nevertheless, it has been shown that if a very large quantity of iron is present, a portion of its oxide is invariably carried down with the antimony. After the oxychloride has been several times washed with water, the Pharmocopœia directs it to be placed in contact with a solution of carbonate of soda for half an hour and then again washed. By this process the whole of the chlorine is removed and pure oxide of antimony obtained. By the long-continued action of water the same result may be effected; but the operation would be very tedious.

Oxide of antimony is described in the Materia Medica as a white powder, fusible at a low, red heat; insoluble in water, but readily dissolved by hydrochloric acid. This solution dropped into distilled water gives a white deposit, which is at once changed to orange by sulphuretted hydrogen. The ready solubility in hydrochloric acid serves to distinguish this, the teroxide, from the higher oxides of antimony, which are much more difficult of solution. Its easy fusibility also serves the same purpose.

PULVIS ANTIMONIALIS.—This is perhaps the proper place to speak of the mixture now introduced to replace the pulvis antimonii compositus of the last, and the pulvis antimonalis of former London Pharmacopœias. Our readers will remember that the latter preparation was an imitation of James' powder, made by calcining together in an open crucible horn shavings and the tersulphuret of antimony. The result of this process was a mixture of phosphate of lime and antimonious acid ($Sb\,O_4$), with a variable but small proportion of the teroxide of antimony and a little antimonite of lime. Antimonious acid is considered inert, and whatever good may have been done by former antimonial powders has been ascribed to the teroxide. The British Pharmacopœia now, however, orders, under the name of pulvis antimonialis, a definite mixture of one part of teroxide of antimony with two parts of precipitated phosphate of lime.

ANTIMONIUM SULPHURATUM is the new name for the antimonii oxysulphuretum of the London College. The directions for the preparation of this compound are the same as before. Tersulphuret of antimony is boiled with caustic soda, and, while the filtered liquor is still hot, dilute sulphuric acid is added in slight excess. The oxysulphuret is thus precipitated and must be washed free from sulphuric acid and sulphate of soda, and then dried. The reactions which take place during the operation are a little complicated, and the results are somewhat uncertain. When tersulphide of antimony is boiled with soda, teroxide of antimony and sulphide of sodium are formed. The latter dissolves some unchanged sulphide of antimony and forms with it a double sulphide. On the other part, the free soda dissolves some teroxide of antimony. Sulphuric acid decomposes both these compounds, and a precipitate is produced which consists of the tersulphide mixed with a variable quantity of teroxide of antimony, and which has, therefore, been called oxysulphuret of antimony. It is of the well-known orange-red colour; it dissolves in hydrochloric acid, evolving sulphuretted hydrogen, and leaving a residue of sulphur. Caustic alkalies completely dissolve it. The teroxide may be separated by boiling with a little acid tartrate of potash (cream of tartar).

ANTIMONIUM TARTARATUM is the new name given to the tartrate of potash and antimony known as tartar emetic. This salt is now directed to be prepared by the simple process ordered in the Edinburgh and Dublin Pharmacopœias. Five ounces of oxide of antimony and six ounces of cream of tartar are mixed with sufficient water to form a paste, which is left alone for twenty-four hours: more distilled water is then added, and the mixture is boiled for a quarter of an hour. The solution is then filtered and set aside for the salt to crystallise.

Tartaric acid, as we have already mentioned, is a bibasic acid, and in this compound one equivalent of the acid is combined with one equivalent of teroxide of antimony and one equivalent of potash, the change which takes place in the above process being simply the replacement of the atom of basic water in the acid tartrate of potash by the equivalent of the oxide of antimony. The formula of the salt as written in the Pharmacopœia is $Sb\,O_3, K\,O, C_8 H_4 O_{10} + 2\,HO$.

There has been some discrepancy among chemical authors as to the proportion of water in potassio tartrate of antimony, and the crystals have been represented as containing one, two, and three atoms respectively. All the most recent writers, however, assign to the salt only one atom.

Tartar emetic crystallises in rhombic tetra- or octahedrons. The Pharmacopœia describes them simply as colourless, transparent crystals which exhibit triangular facets. This description will only apply to fresh crystals, since they readily part with water, and soon become opaque. The powdered salt is said to be sometimes adulterated with cream of tartar. The test of purity given in the Pharmacopœia is a quantitative determination of the antimony in the form of tersulphuret—9·91 grains of which should be precipitated by sulphuretted hydrogen from twenty grains of the tartar emetic. Cream of tartar may be readily detected by adding a very little solution of acetate of lead, acidulated with acetic acid, to a solution of the suspected salt. It is only necessary to add that pure tartar emetic is soluble in water, and slightly also in proof spirit.

In the description of the preparations of antimony, there can be no doubt that the British Pharmacopœia is far superior to the London Pharmacopœia, and the processes for preparing the salts and other compounds of this metal are more simple and intelligible.

REVIEW OF BOOKS.

Treatment of Diseases of the Skin. By Dr. William Frazer, Lecturer on Materia Medica to the Carmichael Medical School. Pp. 174. Dublin: Fannin and Co. 1864.

Many of the works on skin diseases which have lately appeared have been devoted to the difficult and perplexing subject of the classification of these maladies; but Dr. Frazer's work is entirely occupied with their general therapeutical management. After a short introduction, he describes *seriatim* the different classes of remedies employed in the treatment of skin diseases under the heads of alteratives, alkaline preparations, chalybeates, tonics, anodynes, emollients, caustics, irritants, &c. Among the first of the alteratives he places mercury, both as an internal medicine and as an external application, and also highly extols arsenic used for its alterative properties. In other chapters he describes the use of cod-liver oil, of baths and mineral waters, and of poultices, in skin affections, and he concludes his work with a formulary, written in English, containing the proportions of the ingredients of each of the medicines described, and the therapeutical use of each formula. Dr. Frazer is apparently unused to writing and is inexperienced in the art of composition; his sentences are very awkwardly put together and are often of enormous length, and the punctuation is so imperfect that it is sometimes difficult to find out the meaning intended to be conveyed. Still, he seems to have laboured fairly at the

subject and to have consulted the best authorities; and if he had taken a little more time to correct the proof-sheets, or had commissioned some friend to perform this task for him, he would have produced a better work.

Glaucoma, and its Cure by Iridectomy: being Four Lectures delivered at the Middlesex Hospital. By J. Soelberg Wells, Ophthalmic Surgeon to, and Lecturer on Ophthalmic Surgery at, the Hospital. Pp. 86. London: Churchill and Sons. 1864.

At the present moment a very general question among the members of the Medical Profession is as to the practical value of Iridectomy, an operation which is extolled by some surgeons and condemned as useless or injurious by others. The answer generally given to these inquiries is that iridectomy is a cure for glaucoma, and then another question arises, What is glaucoma? The older race of practitioners looked upon glaucoma as a variety of amaurosis, and one of the worst forms of that disease; but since the invention of the ophthalmoscope by Helmholtz, in 1851, and the investigation of the physical conditions of the optic nerve in disease by Jäger and Von Gräfe, the true pathology of glaucoma is said to be discovered. The appearances described are an excavated or cupped appearance of the entrance of the optic nerve, and a peculiar displacement of the vessels at the edge of the optic disc, these phenomena being supposed to be due to an augmented tension of the globe of the eye; and this tension, it is said, can be relieved only by iridectomy, or, in other words, by cutting out a portion of the iris and making an artificial pupil. It is evident that the subject is a very difficult one, and deserves the attention that has lately been bestowed upon it; and notwithstanding the eminent position of those who advocate and practise the operation, its efficacy is not yet by any means universally acknowledged. In the present little work, Mr. Soelberg Wells, who is a strenuous advocate of the operation, describes carefully the symptoms and pathology of glaucoma, and also the different steps of iridectomy and the instruments used in its performance, and we have no hesitation in recommending his lectures as a very useful and opportune contribution to ophthalmic surgery.

A Handbook of Uterine Therapeutics. By Edward John Tilt, M.D., Member of the Royal College of Physicians. Second Edition, pp. 318. London: Churchill and Sons. 1864.

It is little more than a year since we noticed the first edition of Dr. Tilt's work, and the necessity for a new issue proves that it has been acceptable to the Profession. We are now informed that it has been translated into German. It contains a very ample description of the *armamentarium* employed by the Medical practitioner in the diseases of the uterus, some of his weapons being of a moral and a dietetic character, some being in the shape of mechanical appliances, and many in the form of drugs, of which there is no lack in Dr. Tilt's catalogue. A very useful feature in the work is a formulary containing a list of medicinal preparations, with the proportions of the ingredients and the doses to be administered. Since the publication of his first edition, Dr. Tilt has not made many additions to his pages, nor has he introduced any particular novelty in his views. In reference to a late shameful action against a medical man in the country, he still adheres to his opinion that it is unnecessary, when examining a female patient with the speculum, to request the presence of a third party; but in this respect we cannot agree with him, as we think that the practitioner would always be on the safe side in requiring such protection for himself. We cannot, even at this distance of time, forget the monstrous absurdity as well as the infamous audacity of the accusation to which we allude; but it could never have been made if a third party had been present at the examinations with the speculum. Such investigations are by no means frequently necessary, and while to a modest woman they must always be in some measure objectionable, to a female of an opposite character they afford ample opportunities for exaggeration, misrepresentation, and very probably subsequent extortion; so that we still warn our brother-practitioners to beware of using the speculum except in rare cases, and when they do, to secure, if possible, the presence of a third party.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. G. JOHNSON continues his lectures "On the Laryngoscope," his present subjects being autolaryngoscopy, or the examination of one's own larynx, and rhinoscopy, or the examination of the nasal cavities, by means of reflectors. Dr. Johnson relates some interesting cases in which tumours and other affections of the nose were detected by means of rhinoscopy. In reference to the construction of the laryngoscope, Dr. Johnson considers that a *perforated* reflector is unnecessary, although in ophthalmoscopy it is essential; and the difference in the principle involved in the two instruments is explained on the laws of optics and the properties of lenses, which are concerned in the latter case but not in the former.——Mr. T. HOLMES continues his "Contributions to the Practical Surgery of Diseases of Childhood," his subject still being the diagnosis and treatment of congenital innocent tumours. He relates three more cases of this affection, two of which have been previously published, and were both successfully treated by operation; in the third case the tumour was deep-seated in the throat, and was fatal. The child died from inanition, from inability to swallow. As a general rule in the treatment of such cases, Mr. Holmes recommends the early removal of the tumour when it is not in a dangerous position; but, when it is cystic, the cyst may be injected with tincture of iodine, and the walls removed by setons or by dissection.——Mr. H. BEHREND contributes a paper "On the Action of the Bromide of Potassium in inducing Sleep." He relates two cases in which this salt was prescribed: both persons were gentlemen of nervous temperament who had suffered from sleeplessness, but who recovered their rest by the administration of the bromide in doses of twenty-five grains three times a day before meals. Mr. Behrend states that this drug is in all cases easily tolerated, and produces neither disagreeable nor toxical effects.——Mr. A. FLEISCHMANN, in a short paper "On Impregnation," relates a case which militates against a theory advanced to the effect that, in the human female, conception in the first half of the time between menstrual periods produces female offspring, and male in the latter. Mr. Fleischmann's case proves that a male may be conceived in the first half of the period.——Mr. E. H. VINEN relates a "Case of Tape-Worm (*Tænia medio-canellata*) successfully treated with Oil of Male Fern." The case, so far as it goes, contradicts the view of Küchenmeister as to the inefficacy of the oil of male fern in the expulsion of tape-worm.

THE 'MEDICAL TIMES AND GAZETTE.'

Dr. J. S. RAMSKILL communicates a clinical lecture "On Epilepsy," in which he recommends the use of belladonna in the treatment of that disease. He considers that this drug exerts a special tonic action on the sympathetic nerves,

many of which are distributed to the intestines and the viscera of the abdomen, and are concerned in the pathology of epilepsy. Dr. Ramskill relates a case in which belladonna was successfully employed, although other measures probably contributed to the favourable result. The dose of the extract of belladonna was ¼ of a grain, afterwards raised to ⅓ of a grain; and cod-liver oil and the phosphorised oil of the Prussian Pharmacopœia was also administered. A hot pediluvium was ordered every night, and a hot shower-bath, followed immediately by a free sprinkling of cold water every morning. A strong liniment of turpentine was applied to the epigastric region at the time of the fits. The patient was a youth of nineteen years old.——Dr. G. HARLEY continues his Lectures "On the Urine and Diseases of the Urinary Organs," his present subject being the pathological conditions in which uric acid is secreted in undue quantity. The presence of a deposit of the urates is always an indication of some importance, although it does not necessarily imply the existence of serious disease. Dr. Harley describes and illustrates the different forms in which uric acid presents itself under the microscope, some of the forms being very rare, others very common.——Dr. H. OSBORN communicates a paper "On the Action of Water on Lead," and he describes the detection of free hydrochloric acid in a well of spring water. Dr. Osborn considers that the presence of this acid is a very important fact bearing upon the solution of lead by drinking water, and that a safer material than lead should be chosen for the transmission of water. Enamelled iron and gutta-percha are perhaps the safest, but the latter is not very durable, and it imparts besides a disagreeable taste to the water.——Mr. F. BROUGHTON relates a case of "Paralysis relieved by Ice." The patient was a bed-ridden girl, aged twenty-one, and the ice was applied in the method recommended by Dr. Chapman, along the spine, followed by hand-friction. The treatment was very successful, and, indeed, so much so, that in the course of less than three months the patient was able to walk about, and in two months more she was performing the ordinary duties connected with a cottage household.

'THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE:' No. lxxiv., May, 1864.

The present number opens with a paper "On Treatment of Acute Rheumatism" by Dr. ROBERT LAW, who strongly recommends moderate bleeding, with the use of *colchicum*, as the most valuable remedies which he has employed.——Dr. WILLIAM MOORE contributes a paper "On the diagnosis and Treatment of Thoracic Aneurism," relating four cases of this disease, but recommending nothing new in the treatment.——Dr. P. C. SMYLY gives a short paper of "Notes in Medicine and Surgery," his present subjects being the condition of the larynx in some forms of phthisis, and the treatment of anthrax by pressure.——Dr. T. W. BELCHER communicates a very learned paper "On the Hebrew, Mediæval, and Modern Leprosies," tracing the history of this disease, or of the diseases which have gone under this name, in the different ages of the world.——Dr. ALFRED H. M'CLINTOCK offers some further observations on "Missed Labour," having received from practitioners in different parts a number of communications bearing upon this subject, which, it will be recollected, Dr. M'Clintock very ably treated in the preceding number of the 'Dublin Quarterly Journal.'——Dr. HARDY relates a case of "Large Polypoid Growth of the Uterus in a Young Girl," the tumour being removed, but the case eventually terminating fatally.——Dr. CHARLES KIDD contributes a paper on "Chloroform in Midwifery Practice," in which he defends the use of this agent against the attacks of those who deprecate its employment.——Mr. EDWARD HAMILTON offers some contributions to the "Surgery of the Rectum and Anus," his present subject being the treatment of hæmorrhoids by the *écraseur*.——Dr. HERMANN WEBER writes some "Notes on the Climate of the Swiss Alps, and on some of their Health-Resorts and Spas," the present paper being devoted especially to the cantons of the Grisons, St. Gall, and Appenzell. The paper is a very elaborate one, and is written, in a great measure, from the author's personal observations in the localities described.——Dr. GEORGE H. KIDD has a paper "On the Use of the Drainage Tube for the Removal of Fluids effused into the Cavity of the Pleura," and he relates an illustrative case which occurred in his own practice, showing the utility of the instrument.——Mr. MAURICE COLLIS makes some practical observations "On the Treatment of Organic Stricture of the Urethra," by means of sea-weed bougies, the *laminaria digitata* being the material employed. It seems probable that this sea-weed will become extensively used in obstetric and surgical practice.

THE 'SOCIAL SCIENCE REVIEW.' EDITED BY B. W. RICHARDSON, M.A., M.D. MAY, 1864.

The present number of this journal contains a number of interesting original articles, on subjects which may appropriately be said to belong to the department of social science. DR. RICHARDSON continues his papers "On the Diseases of Overworked Men," treating particularly the instances of speculators, medical men, clergymen, lawyers, and actors. He attributes much of the petulancy and irritability of barristers to the confined air they breathe, the great amount of their mental labour, and the inconvenience of the forensic costume; he condemns the use of the brougham by the medical man as detrimental to his health, by depriving him of air and exercise. In an article "On the Cure of Habitual Drunkenness," some suggestions of a very useful character are thrown out as to the treatment of this failing, which may truly be considered a mental disease; and the "Relation of Crime and Insanity" treats a very difficult subject in a most philosophical manner, adducing many cases, obtained from prison records, in support of the views advanced by the writer. The view taken is, that many persons are shut up in prison for offences which are really attributable to the aberrations of a disordered intellect, and that such cases are not improved by such repressive means. A paper "On Ozone," gives a brief but interesting sketch of this important form of oxygen, detailing the history of its discovery, its properties, its mode of preparation, and the important uses to which it will probably before long be applied, as a disinfecting, deodorising, and purifying agent.

THE MEDICAL CIRCULAR.

WEDNESDAY, JUNE 1, 1864.

MEDICAL NATIONALITIES.

A philosophic student of the History of England might perhaps suppose that, as the different sections of the British Isles have been brought together under the control of a single monarchy, their religious, legal, and medical institutions ought to be substantially the same; but such is far from being the case. The Reformation effected in the reign of Henry the Eighth has been inoperative in converting the great majority of Irishmen to Protestantism, or in preventing Presbyterianism from becoming the established religion of the Scotch. In matters of law, the same discrepancy prevails; and although Englishmen, Irishmen, and Scotchmen are all common subjects of one crown, yet a debt contracted in one part of our islands cannot be recovered in another; a marriage-custom which is binding in one is valueless in another; and a difference, or alleged difference, in religious opinions of the marrying parties is still thought a sufficient cause for dissolving the matrimonial bond.

In the domain of Medicine, all artificial distinctions have been for some years practically abolished, except such as arose from the operation of certain charters or Acts of Parliament conferred upon some of the Medical Corporations, and which seemed to endow those bodies with special privileges. But it cannot be said that any of those guilds abused or overstrained the powers entrusted to them. The College of Physicians of London, which, by the charter granted to it by Henry the Eighth, possessed an absolute authority over the physicians of former days, and could fine and imprison illegal practitioners of medicine, had long allowed its powers to sink into abeyance; and it lately fell into a position of quiet, though dignified respectability, trusting rather to the prestige of its character than to the exercise of its legal rights. The Society of Apothecaries of London, entrusted with the execution of the Act of 1815, possessed, indeed, the power of instituting prosecutions of illegal practitioners; but, as no funds were supplied for the purpose, and as the decision in such cases was left to a jury, the results were almost always unsuccessful, and the expenses enormous. The institution of the County Courts, however, partially remedied the evil, and made the prosecution of illegal practitioners comparatively easy. The Dublin Apothecaries' Hall possessed, by Act of Parliament, the control of shops for the compounding and dispensing of medicines in Ireland, and the power of granting certificates to practise pharmacy in that country; but, from want of funds, it is now unable to exercise its powers. Some Scotch and Irish Colleges also held some local, though unimportant, privileges, and all the Universities possessed the power of granting degrees in medicine; and some of them had the additional right of conferring licences to practise it, under certain restrictions. But notwithstanding all these diversities and anomalies, no practical or substantial harm was done to the honourable practitioners in medicine; if a man wished to practise as a physician he was quite at liberty to do so, and the College of Physicians of London, whatever moral influence they might exert against those who were not within their own pale, never interfered, of late years, to punish those who infringed on their privileges. The surgeons might or might not belong to a College of Surgeons, as none of the Surgical Colleges had a right to interfere with their practice; and if a man chose to act as an apothecary in England and Wales—that is to say, to prescribe medicines and to supply them in a medical case—he was very seldom interfered with, whether qualified or not, except perhaps by the practitioners in his own neighbourhood, who might, perhaps, call out for fair play. With regard to national reciprocity in medical privileges, there was not much, in reality, to complain of. The British metropolis, being necessarily the seat of government and the focus to which all the wealth and power of the empire were attracted, naturally invited many Scotch and Irish practitioners of medicine, who, by an easy conformity to certain collegiate conditions, were welcomed into English practice; and, *vice versâ*, the English practitioners might, if it so pleased them, migrate to, and practise in, Scotland or Ireland; and the whole of our military, naval, and colonial medical appointments were thrown open indiscriminately to English, Irish, and Scotch.

But still it was thought that too many restrictions existed, and that there was not yet a sufficient fusion of the national medical elements to satisfy all parties. The constant theme of the medical reformers was the diversity of conditions under which medical degrees, diplomas, and licences could be obtained, and the necessity of breaking down corporate monopolies in all parts of the kingdom. This latter object was certainly effected by the Act of 1858, which melted down all the Medical Corporations—good, bad, and indifferent—in one common crucible; and recognising the licences of all of them as exactly alike in the eye of the law, left the heads of each of them to fight their own battles with one another and with the public. Assuredly, the measure of 1858 was a liberal one in every sense of the word; for while it ignored all exclusive privileges hitherto possessed or claimed by the Medical Corporations, it proclaimed free trade in medicine and quackery, prohibited the colleges from suppressing or discouraging empirical theories or practices within their own bodies, and directly legalised quackery, by placing it on a legal level with, though in opposition to, legitimate medicine.

However, we have obtained the Act of 1858, and we must make the best of it. It might, perhaps, be thought that, although we have succeeded in getting nothing in the way of suppressing quackery, yet that we might promote and encourage uniformity of practice among ourselves, and bring the requisitions of the Educational and Examining Medical Bodies into harmony with one another. But this is an object which, though it legitimately falls within the scope of the Act, we have hitherto entirely failed to accom-

plish, in consequence of the Medical Nationalities, which we have chosen as the title of the present article. The Universities of London, Dublin, Oxford, and Cambridge refuse, and we think with reason, to abrogate their rights to demand of their *alumni* sufficient evidence of preliminary education; and the Scotch Universities, on the contrary, refuse to make preliminary education compulsory before the commencement of medical study. Some of the corporations claim the exercise of privileges to which they are clearly not entitled; some, by elevating their standard, are outbidden by others less scrupulous than themselves; some, while demanding a *minimum* of education, claim for their candidates a maximum of honour and esteem. If we ourselves offered any opinions upon these and other matters, or if we specified more distinctly the conflicting practices of the English, Scotch, and Irish corporations, we might also lay ourselves open to the charge of undue national prejudice, which charge we are anxious to avoid incurring.

On one other subject in connexion with our theme we are induced to make a few remarks, namely, on the British Pharmacopœia, which illustrates the above views as to the difficulty of overcoming national prejudices; and we the more readily comment on this subject as we believe the English section of the empire to be in fault in their reception and treatment of the book. The great anomaly so often exposed, and so loudly complained of in reference to our Pharmacopœias, was the difference in the drugs themselves, in the mode of their preparation, and in their strength, in the books published respectively by the London, the Edinburgh, and the Dublin Colleges; and it was a matter of universal desire to harmonize the contents of these three books into one consistent whole, which should be alike available to medical practitioners in all parts of the British Islands, and in all the colleges and dependencies of the British Empire. Many of the formulæ in the London Pharmacopœia might appear objectionable to the compilers of the Dublin or Edinburgh Pharmacopœia, and, *vice versâ*, the contents of the latter might not be generally acceptable to London practitioners. But nobody ever supposed that the discrepancies in any of the books indicated either ignorance or bad faith; they merely amounted, at the worst, to differences of opinion, which might be reconciled by mutual concessions.

It is, therefore, not without sorrow that we have heard of an opposition to the British Pharmacopœia in many influential quarters in England. If this opposition had been instituted against the errors of the book, it would have been in some respects justifiable; but as we understand the case, its opponents object to it because they do not choose to study, or are not able to understand the changes which the book presents in comparison with the last London Pharmacopœia. Such an objection would, of course, be equally valid in the case of *any* new Pharmacopœia, but especially of *any* which sought to harmonize three already in existence. But the reconciliation of the three was the problem to be accomplished; and unless we return to the use of the three separate Pharmacopœias, we are, as we conceive, bound to make the best of that which is now presented for our acceptance.

SUMMARY OF THE WEEK.

VACCINATION AND THE PREVENTION OF SMALL-POX.

A deputation of the Epidemiological Society lately had an interview with the Lord President of the Council and the Vice-President, in order to represent to them the necessity which exists for an amendment of the present Vaccination Laws. We have frequently called attention to the flagrant defects of the present system, and we are glad to find that the deputation urged amendments of the law in respect to the registration of vaccination, the form of proceeding against negligent parents, the supervision of vaccination, and the arrangements for public vaccination. The last of the points referred to by the deputation was the most important of all—namely, the inexpediency of entrusting the control of public vaccination to two distinct Government Boards, and the propriety of transferring the powers at present exercised by the Poor-law Board to the Privy Council. Nothing, in fact, can be more absurd than to confer upon the Poor-law Board the control of public vaccination; that Board knows nothing at all about the subject, nor does it comprise among its number any medical or other competent authority who does know. The consequence is, that vaccination is left to be regulated by the Poor-law Guardians throughout the country, who are utterly incompetent to the task imposed upon them, being necessarily ignorant of the precautions essential for securing efficient vaccination, and quite unable to know whether the vaccinators perform their duty or not; added to which, by the traditional policy of Poor-law Boards, they pay the vaccinators so badly as to make the discharge of their office quite unremunerative. It should also be stated that the connexion of vaccination in any shape with the Poor-law Boards is calculated in itself to make the operation unpopular, as implying that those who avail themselves of the advantages of gratuitous vaccination are in some way receiving parochial relief. We are aware that such is not the fact, but it is difficult to persuade the common people that a gratuitous medical service in one case is considered to pauperise the recipient of the favour, and not in another case, especially when the guardians who confer the boon are exactly the same persons. This circumstance, and the known and proved incompetence of the guardians to regulate vaccination in an efficient manner, ought to induce the Government at once to take the duty from them and to place it in other hands.

THE FORTHCOMING ELECTIONS AT THE COLLEGE OF SURGEONS.

At the approaching anniversary meeting of the Fellows of the College of Surgeons, three vacancies will be declared in the Council—one by the death of Mr. Green, and the other two by the retirement, in rotation, of Mr. Gulliver and Mr. Hancock. It should be stated, however, in justice to Mr.

Hancock, that his retirement is technically caused by the circumstance that the gentleman whose place he supplied would have gone out of office at the next election, and therefore there is no doubt that Mr. Hancock, who was elected only last year, will be re-elected. For the vacancy caused by the death of Mr. Green, Mr. Curling will offer himself for election; and Mr. Le Gros Clark is also a candidate for a vacant seat in the Council. Both these gentlemen are estimable men, and their election would give general satisfaction; and the only question against the election of both of them is the chance of success possessed by Mr. Gulliver, who, we understand, offers himself for re-election, and who, it will be recollected, was somewhat unhandsomely treated last year in being passed over as an examiner, on no other ground than that he was not an hospital surgeon.

THE DIFFICULTIES OF THE ARMY MEDICAL DEPARTMENT.

We publish in another part of our Journal the document addressed by the Royal College of Physicians of Edinburgh to Lord Palmerston, on the subject of the grievances complained of by the Army Medical Officers. In this very temperate statement the whole state of the question is fully explained, and the Government cannot now assert that they do not understand the nature of the complaints made against the Medical Department of the Army. We do not hesitate to confess that we fail to perceive so clearly as some of our contemporaries do, the hardships endured by the Medical Officers of the Army, and we attribute to other causes than those which are alleged the falling-off of candidates for the service. It is, however, a hopeful sign of the times that Medical men are in such request that a large public department has to go begging for candidates; and we wish that the same were the case with the Poor-law Medical Service, which, if subjected to the same wholesome pressure, would treat the Poor-law surgeons with more respect than they now do. But still, we have no desire to ignore the complaints made by the Army Medical Officers, or to defend the Government against what certainly seems to be a gross breach of faith in rescinding the Royal warrant procured by Lord Herbert; and we hope that the heads of the department, now that the facts and grievances are fairly laid before them, will set themselves at once to consider the subject in a fair and liberal spirit, instead of pretending to shut their own eyes, and endeavouring to blind the eyes of the Legislature and the public.

THE SUPERVISION OF EXAMINING BOARDS BY THE MEDICAL COUNCIL.

The Medical Council has been apparently very unwilling to exercise a power, which it undoubtedly possesses, of personally superintending the mode of examination pursued at the different Examining Bodies. There cannot be a doubt that some of these Boards are exceedingly lax in their mode of granting diplomas and licences—some of them from the very restricted nature of the subjects required to be "got up" by the candidates, and some from the loose way in which the examinations are conducted. The presence of an inspector sent from the Medical Council, or the mere probability of his coming, would have the effect of stimulating the energies of the Examining Boards, and those of them which were conscious of doing their duty would have nothing to fear from the visitation. As to the objections to this supervision, they appear to us to be very feeble. One is, we believe, the expense which such a proceeding would entail; but, really, the Council has been spending money with such a liberal hand of late, that it might afford a little more for this very necessary and salutary duty, which need not be performed very often. As to another objection which we have heard urged—namely, that no one person would be competent to criticise the examinations in all the subjects proposed for examination at a given Board—we answer, that he would not be required to act as a critic or a judge of the examinations, but merely as an observer or spectator of what was done, with a view of reporting to the Council. It would be also very easy to furnish copies of the written questions and answers given at the Examining Bodies, so that they might be inspected by the General Council. No Examining Boards would object to such supervision, except such as were conscious of falling short of the requirements essential to the efficient scrutiny of the attainments possessed by candidates for medical and surgical licences.

THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH ON THE STATE OF THE ARMY MEDICAL DEPARTMENT.

The following memorial on the subject of the present condition of the Army Medical Department has been addressed by the Royal College of Physicians of Edinburgh to Lord Palmerston. It represents in very clear and moderate language the grievances complained of by the Army Surgeons:

"To the Right Honourable Viscount Palmerston, First Lord of Her Majesty's Treasury,

"The Memorial of the Royal College of Physicians of Edinburgh, Humbly sheweth,—

"That the Royal College of Physicians are charged with the licensing of medical practitioners, and are therefore bound to watch over the interests of the Medical Profession and of the public.

"That the attention of the College has been frequently drawn to the very unsatisfactory condition of the Medical Department of the Army; and that the evils often complained of have now become so aggravated that they consider themselves called upon, in the public interest, to bring the subject directly under your lordship's notice. Your memorialists would, therefore, beg respectfully to lay before your lordship the following statement of facts:—

"Previous to 1854 public attention had not been specially directed to the Medical Department of the Army; and though the officers of that Department considered that they laboured under various hardships, a sufficient supply of medical men for the wants of the service could always be obtained. On the outbreak of the Crimean war, it was soon discovered that there was a great deficiency of medical officers; and this deficiency was subsequently the cause of a great amount of suffering among the troops. As it was found impossible to obtain a sufficient supply of regular assistant-surgeons, passed according to the requirements of the Army Medical Board, a number of civilians were engaged as acting asssistant-surgeons, to perform the duties of commissioned assistant-surgeons. Notwithstanding, the Medical Department of the Army confessedly broke down, in consequence, not of the inefficiency of the officers, but of the smallness of their number.

"In 1856 a Select Committee of the House of Commons considered the whole subject, and recommended in their report that the pay of assistant-surgeons should be in-

creased, and that means should be taken to make it unnecessary in future to have recourse to civil assistants.

"In 1857 a Royal Warrant was issued, which raised the pay of assistant-surgeons to ten shillings per day.

"In 1858 a new Royal Warrant for the Medical Department of the Army appeared, which was justly regarded as a great boon by the officers of that service. Among other important concessions, it was ordered that medical officers should have a certain rank relative to combatant officers, and that this rank should carry with it all precedence and advantages, with the single exception that the presidency of courts-martial should always be held by combatant officers. The result of these concessions was, that an abundant supply of eligible candidates presented themselves, so that the authorities were enabled to raise the standard of examination and of qualification.

"Complaints, however, were soon made that the Warrant of 1858 was not fully carried out, and especially that the regulation with regard to relative rank was systematically violated.

"On the 28th of March, 1861, a new Warrant was issued, ordering that assistant-surgeons, promoted after that date, should rank with majors, but junior of that rank; this order being in direct contravention of the Warrant of 1858, which directed that medical and combatant officers should rank according to the date of their commissions. At the same time, a reduction in the number of assistant-surgeons was made, whereby additional duties were thrown upon the rest, and it became very difficult for them to obtain leave of absence.

"In 1862, an order was issued, that staff and regimental surgeons should, in their annual reports, answer a variety of questions with respect to the assistant-surgeons who had served under them during any part of the preceding year. Some of these questions were of such a nature that one gentleman should not be called upon to answer them in regard to another. Thus, the surgeon was required to state the character of his assistant-surgeon as to sobriety, correctness of general conduct, temper, and similar points. This was felt degrading to the character of staff and regimental surgeons, as constituting them spies upon their juniors, whereby suspicion and distrust were necessarily engendered.

"In March, 1863, a new Warrant was issued, which restored, though not in its full integrity, the relative rank conceded by the Warrant of 1858.

"The effect of the changes which have been introduced since 1858 has been deplorable. Many medical officers have resigned, and it has been found impossible to supply their place. For some time past the number of candidates at the competitive examinations has been much below the number of vacancies; and of these candidates a large proportion have been found grossly ignorant, and have been rejected, which clearly indicates that the army is unpopular among that class of medical men whose services it would be for the interest of the department to secure. So difficult has it been to procure candidates, that the limit of age of entrance has been raised from twenty-five to thirty; and that lately the Director-General has advertised for acting assistant-surgeons, who are eligible up to the age of forty years, and who are to take the place on home service of commissioned assistant-surgeons.

"Your memorialists, viewing with great anxiety this very unsatisfactory state of an important branch of her Majesty's service, would beg respectfully to urge upon your lordship the necessity for a reform of the following grievances, to which military medical officers are subject:—

"First, in consequence of vacancies not having been filled up, promotion has become so slow that no assistant-surgeon now entering the service can expect to become a surgeon in less than fifteen years.

"Second, in consequence of the deficient number of medical officers in the army, it is with great difficulty that leave of absence can be obtained.

"Third, in consequence of the appointment for home service of acting assistant-surgeons, the commissioned assistant-surgeons will be almost exclusively employed on foreign service, and will be deprived of their proper turn of serving in this country.

"Fourth, the system of confidential reports, of an inquisitorial character, is felt as a degradation, both by those who are required to draw them up, and by those to whose conduct they refer.

"Fifth, medical officers are required to superintend the branding of deserters, and are thereby placed in a position which no professional gentleman should be called upon to occupy.

"In name and by authority of
"The Royal College of Physicians,
"JOHN GRAHAM MACDONALD BURT,
"President.

"Edinburgh, 12th May, 1864."

GENERAL CORRESPONDENCE.

THE BRITISH PHARMACOPŒIA.

To the Editor of the Medical Circular.

SIR,—I am sorry I cannot agree with you as to the excellence and utility of the new Pharmacopœia. It reminds me forcibly of the truth of the old saying, "The more cooks the worse kail;" and I cannot doubt but, if its compilation had been left to one single individual, such as the pre-eminent Professor of Materia Medica at Edinburgh, the Profession would have procured such a work as would have been useful to them and honourable to the compiler.

Without previously perusing the work, I had it sent to me, and now find, in return for my outlay, that I am possessed of a book almost useless for any practical purposes. I find no means of distinguishing betwixt new and old formulæ; I find nothing said as to the action of the several preparations; nothing as to their uses in the several and many forms of diseased action; and nothing to guide even the druggist, or tyro in medicine, as to *the doses* which can safely be administered—such being a few only among its many defects. I must say that the purchasers of the work are placed in a very hard position, in having bought a very expensive book, of which they can make but little use. And further, I would suggest, in common fairness and justice, either that the work already issued and paid for be recalled, and the purchasers recouped, or that they have presented to them an appendix, remedying the present palpable deficiencies. We gain our money too laboriously to have it thrown away on what is useless to us.

I am, Sir, yours, &c.
A YOUNG PRACTITIONER.

Banks of the Thames, 25th May, 1864.

THE LICENCE OF THE COLLEGE OF PHYSICIANS.

To the Editor of the Medical Circular.

SIR,—I am desired by the President of the Royal College of Physicians of London to request that you will be good enough to insert the following statement in reference to an inaccuracy in the subjoined passage of a leading article in your Journal of May 25th:—

"But it so happened that the other corporations, so far from conforming to the recommendations of the Medical Council, had positively disregarded them, and headed by the College of Surgeons, *and sanctioned by the Council itself*, had returned to or maintained their previous regulations; and the Society of Apothecaries, therefore, had no choice in the matter but to rescind their regulations published in 1861 and 1862, and to require only three years' attendance on lectures and hospital practice; and in so doing they *followed* the College of Physicians of London, the College of Surgeons of England, and nearly the whole of the Medical Corporations in the United Kingdom."

Every candidate for the College licence (except in cases specially exempted) is required to produce satisfactory evidence of having been engaged in professional studies *during four years*, and the time of commencing professional

studies is understood to be the time of commencing studies at a Medical School, in accordance with the recommendations of the Medical Council.

Three of the four years of professional study required by the College regulations must have been passed at a recognised medical school or schools, and the other year, *completing four years of professional study*, must have been passed at a medical school, hospital, infirmary, or dispensary recognised by the College.

The College, since its regulations were issued in 1860, has never required less than four years of professional study, and these four years must be passed either at a recognised medical school, hospital, infirmary, or dispensary; it cannot, therefore, with truth be said of any corporations requiring only three years' attendance on lectures and hospital practice, that, "in so doing, they *followed* the College of Physicians of London."

I am, &c., HENRY A. PITMAN,
Royal College of Physicians, London, Registrar.
May 28th, 1864.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, May 10.

Mr. FERGUSSON, Vice-President, in the Chair.

Mr. CHARLES HAWKINS communicated a paper, by Dr. George B. Brodie, on

STATISTICS OF QUEEN CHARLOTTE'S LYING-IN HOSPITAL.

The author commenced his paper by observing that in consequence of a notice having appeared in one of the Medical Journals for 1862 relative to the mortality observed in the lying-in hospitals of London, and in Queen Charlotte's Hospital in particular, the present paper was commenced to give the desired information, and to show that all the deaths which took place in the Hospital were not from puerperal causes. For the last thirty-six years, from 1828 to 1863 inclusive, the registers have been carefully kept, but no detailed accounts published; during this period 7,736 patients (producing 7,824 children) were delivered in the Hospital; of this number 3,611 were single women, who are admitted if it is their first pregnancy, and of these 126 died, the remaining 4,125 were married women, of whom 72 died. The great mortality existing amongst unmarried women on their passage through the puerperal state was then touched upon, and some reasons were given to account for this fact, of which the separation from friends, their living in seclusion for some months previous to their admission into the Hospital, exposure to atmospheric changes and semi-starvation, all tending to depress the mental and bodily powers, were the principal. Some reference was also made to the married patients, who are often admitted into the Hospital in labour very shortly after they are married, and a case in illustration of this which fell under the author's notice was given, in which the patient walked from the church to the Hospital, registered her letter as a married women, and was admitted in labour within three days from that date; the mortality amongst the married patients would, therefore, be considerably diminished if it were not for the fact that so many are exposed during the period of gestation to the same depressing causes as the single patients. The first table (Table I.) showed the numbers of deliveries, and number of deaths, with the death-rate for every year since 1828. The number of women delivered at their own homes annually was also given, but of these, there being no trustworthy records, no further notice was taken.* A detailed investigation into the cause of death in each year was then entered into, the results of which were given in Table II.; for four years the Hospital presented a clean bill of health. Puerperal fever (under which denomination its many varieties were necessarily included) was found to have been present in 123 cases, no less than 99 of which were in primaparæ; seventy-five out of the 123 cases were among the single women; the death-rate from this cause was 1·57. The various periods of the year in which these cases of puerperal fever occurred was given in Table III., the result of which went to show that the healthiest months—or the months in which the least number of deaths happened—were October and August; after these the following order was observed:—November, April; January, July, September, December; May, June; February and March. For eight years the wards were free from puerperal fever. Mania was found to have been present in sixteen instances, fifteen of these were in primaparæ, and no fewer than eleven were single women; in twelve out of the sixteen cases the age of the patient was between twenty and twenty-four. The remaining cases referable to puerperal causes, as post-partum hæmorrhage, ruptured uterus, coma, exhaustion, &c., were 22, making, with the puerperal fever and mania, a total of 161. Of the non-puerperal causes, phthisis and diarrhœa were the principal; pneumonia and some of the eruptive fevers being also present; making altogether a total of forty-one, which, with the 161 deaths from puerperal causes, gives the original number of 202. Another table gave the total number of cases admitted in each month during the thirty-six years, with the corresponding number of deaths from all causes during the same period, with a result very similar to that obtained when puerperal fever alone was observed. The death-rate of the Hospital was then entered into, which was shown to be, for the married patients, 1·84; for the single patients, 3·48; for both together, 2·6. The death-rate has varied considerably at different times; it was at its highest in 1849—the year of the cholera—and has varied from that to *nil*. In all cases but one, in which the death-rate was unusually high, the cause was found in the fact that the deaths were principally amongst the single women; for instance, in the most fatal year, 1849, the deaths of the single patients were just double the married; in 1850, there were eight single and no married; in 1860, whereas fourteen single women died, there were but four deaths amongst the married patients; in this lies the cause of the comparatively high mortality of Queen Charlotte's Hospital. In another table was given the death-rate observed at the Rotunda Hospital, Dublin; it was obtained by comparing the deaths with the number of admissions during the last thirty-six years, and was found to be 1·45 per cent. At the British Lying-in Hospital, the death-rate from 1849 to 1861 inclusive was ·69; the number of admissions was very small, hardly exceeding 1,550 patients. Both of these hospitals, however, profess only to admit married women. The author went on to remark that, in his opinion, the high death-rate of the Queen Charlotte Hospital was, in a great measure, due to the fact mentioned at the commencement of the paper, that so many of the married women are exposed during the period of gestation to many of the depressing moral agencies of a single life. A comparison was then drawn between the mortality of a lying-in hospital with patients delivered at their own homes; the out-door midwifery department of St. George's Hospital (restricted to married women) was taken as an example; the number of patients delivered was 2,800; the number of deaths eleven (one of these was a case of abortion, and happened in the hospital); the death-rate, therefore, was ·38, very favourable when compared with 1·84 or 1·45, and this notwithstanding the filth and poverty in which they live. The author concluded this portion of the paper with a brief account of the foundation of the Hospital, and the following sketch of the ventilation and plan:—The Hospital contains two floors for the reception of patients, one for married and one for single women. On each floor are six wards, containing three beds each, in which the patients are delivered, with an average of 1,000 cubic feet space to each patient; but as each ward has not always its complement of three patients, the actual quantity of of cubic space to each bed is sometimes increased. On each floor also is one conva-

* The total number of patients delivered at their own habitations from 1828 to 1863 inclusive was 10,858. The number of patients, therefore, delivered in and out of the Hospital during this period was 18,594.

lescent ward, containing six beds; the walls of the wards are made of Parian cement, painted and varnished so as to enable them to be thoroughly well washed; throughout the building runs a corridor 84 feet long by 7 feet wide, having a window at each end, and a large staircase opening at its centre, in the roof of which is a ventilating opening, protected by a cowl; the whole of the Hospital is thus completely ventilated. Each individual ward is ventilated by means of an opening in a shaft that is carried to the top of the building, an Arnott's ventilator in the chimney, and an opening (that can be closed) over the door, communicating with the corridor; the windows are on the plan adopted at St. George's and the Middlesex Hospitals, which form ventilators of themselves. In each ward there is a constant supply of hot water, and the corridors are heated by means of pipes containing hot water. The water-closets, one on each floor, are external to the building, and approached through an ante-room, so as to be entirely cut off from the rest of the building. The soil is for many feet of the best gravel, and every attention has been paid to the drainage. As soon as a patient is able to be moved from the ward in which she has been delivered, she is placed in the convalescent ward, where she remains until she leaves the Hospital. As soon as three patients have been delivered in a ward, it is not again used until it has been well cleaned, as well as the beds and bedding; by this plan each ward remains vacant for ten days or a fortnight before patients are again received into it. When a case of puerperal fever occurs, the ward is freshly whitewashed, and the walls thoroughly washed down (in some cases repainted), the bedding purified and remade, and the ward not occupied again for at least a month. Everything has been done, both in the construction of the building and in the arrangements for the management of the patient, with a view to render them as little liable to disease as possible. In Section II., facts having more direct reference to the fœtus were investigated. Of the total number of labours—7,736—there were 2 cases of triplets and 84 twin births. Out of the 7,650 single births, there were 235 abnormal presentations, or 1 in every $32\frac{1}{2}$ cases, with a fatal result to the mother in 5 cases, or 1 in 47 cases: the head of the child, therefore, presented in 7,415 instances; but of these the face presented in 15 cases, or 1 in $494\frac{1}{3}$ cases, and in 103 instances the child's head passed with its face looking towards the pubis of the mother. The funis was prolapsed in 22 cases, being met with once in every 348 cases; of the 22 cases 14 of the children were stillborn; in 12 cases it was prolapsed before the head, and of the children 9 were stillborn; in 6 before the feet, and of the children 3 were stillborn; 2 were cross births, and both stillborn. The upper extremity presented in 21 cases, or 1 in 364 cases, the breech in 139 instances, being 1 in 55 labours; of the children in these 139 cases, 88, or 1 in $3\frac{7}{10}$ were still born. The lower extremity presented 49 times, or 1 in 156 labours; eighteen of the children, being 1 in $2\frac{7}{10}$, were stillborn. Placental presentations occurred 4 times, or 1 in $1,912\frac{1}{2}$ cases. Twin labours were then gone into, and a table given to show the presentation in each case; in by far the greater number of instances—namely, in 39 out of the 84 cases—both children presented naturally; next to this, cases in which the head of the first child, and the nates or inferior extremities of the second child presented, were most frequently met with—namely, in 22 cases. The first child presented with the nates in but 11 cases, and the lower extremity was similarly met with in but 6 cases. This section concluded with a notice of the operations. Craniotomy was employed in 21 cases, being 1 in $361\frac{1}{2}$ cases, and was followed by the death of the mother in 6 instances. Forceps were applied in 49 cases, or 1 in 158 instances, and their application was followed by the death of the mother in 10 cases, or 1 in $15\frac{3}{4}$ cases.

Dr. WEBSTER, after a few remarks on the value of the paper, said that, having paid considerable attention to statistics of disease ge nerally, he would make a few remarks on several points in the paper. The author had found that the mortality of the single women was double that of the married. Admitting the influence of distress of mind and privation to which the author had alluded, he thought it ought to be taken into consideration that the single women were always admitted for their first child, and he believed that it was admitted that there was greater danger on a first than on a future delivery. The paper was of great importance, too, as regards the question whether it is desirable or not to have lying-in hospitals. It was a question which had been discussed throughout Europe. At one institution with which he (Dr. Webster) was connected—the St. George's and St. James's Dispensary—there had been during the last seven years 1,515 deliveries and not one death. All these women had been delivered at home. In the British Lying-in Hospital there had been 1,500 deliveries in that institution, and again no deaths. It was singular, the speaker continued, that there should be no difference when the great difference of the position of the patient was taken into consideration:—in one every possible comfort, in the other great poverty and distress. He (Dr. Webster) had found that during the last seven years 175 women had died in the lying-in hospitals of London generally, and, as stated, during a like period, there had not been one death in the St. George's and St. James's Dispensary out of 1,515 cases. This, he thought, told against the lying-in hospitals. In Vienna the mortality had been thirty per cent. Then as to puerperal mania. There were seventeen deaths from this cause, eleven single women and six married, but there was no statement as to the number of patients who had had the disease and had recovered. At Bethlehem Hospital the mortality from puerperal mania was only four and a-half per cent. Dr. Webster, after again remarking on the great interest of the paper, asked for information as to the deaths of the out-patients.

Mr. CHARLES HAWKINS said that, having introduced Dr. Brodie to the Society, he could not let the paper pass without some observations. He felt sure that the Society would be glad to find one of the name of Brodie again working in the Profession. It was to be hoped that the author of the paper would keep his uncle's career in view. Mr. Hawkins then said that when he first began to pay attention to the mortality of Queen Charlotte's Lying-in Hospital he was much startled by the great mortality, and he felt that it was a very serious question whether lying-in hospitals should be supported or not. For the construction of the present Queen Charlotte's Hospital he alone was responsible, and he was prepared to defend it. The difference in the mortality in the out-patients and the in-patients was very striking, and at one time it might have depended on the building. He wished to know from Mr. Fergusson if there was a great difference in the mortality at the King's College since rebuilding the hospital. He believed he was right in saying that at the old hospital everything as regards hygiene was as it ought not to have been, and the new hospital had, no doubt, been constructed upon the most approved principles. It would now be interesting to know what difference there was in the course of disease since the new hospital had been occupied. The answer to this question would be important, as some people put great stress on the construction of hospitals, and seemed to think that if the hospital was built in a proper manner death would vanish. He had understood that the patients did as well in the old as in the new hospital. Then as to the mortality in Queen Charlotte's Hospital, he could not speak as an authority with regard to the particular disease, but he was satisfied that it was brought in, and not contracted in the Hospital. He belived that the author had stated the real causes of a great part of the mortality. It was because this Hospital admitted single women. He (Mr. Hawkins) had paid much attention to this point, and believed that nothing could be more wretched than the condition of many of these patients. Wherever they had been delivered, the result would have been the same. It might be a question whether it was wise, in a social point of view, to take married women from their homes during their confinements, but he had no doubt the mortality in single women would be greater if they were not admitted. It was often their only hope, and in a vast number of instances he felt satisfied that it prevented child-murder, if not self-destruction. At Vienna, at one time, the mortality was 30 per cent. The beds were then divided equally between the midwives and the medical men. The result was that on the side of the

midwives the mortality fell. The reason doubtless was this, that on the medical side the students who delivered the women made post-mortem examinations, and were engaged in attending patients in the general hospitals. Mr. Hawkins then remarked on the admission of women for delivery, into general hospitals. He did not consider it advisable, and in lying-in hospitals he thought it much better that there should be several small wards than one or two large rooms, as is the case usually in the foreign hospitals, and that lying-in hospitals should never be large. He concluded by saying that he considered that when the author's paper was analysed the Society would give its verdict in favour of Queen Charlotte's Lying-in Hospital.

Mr. FERGUSSON said that, not being prepared for Mr. Hawkins' question, he must not be taken as pledging himself when he stated that he was under the impression that he had found no difference in the mortality nor in the course of diseases at King's College Hospital since the new building was erected. There was, he said, still a great difference of opinion as to the mode of carrying out the arrangements for ventilation. He could not speak exactly as to the deaths from parturition, but he believed that there had been one death a few months ago, and a short time afterwards another. Dr. Priestley had since limited the number of admissions.

Mr. CHARLES HAWKINS thought Mr. Fergusson's answer to his inquiries of the utmost importance. It went to show that in the old and new King's College Hospital there was no difference in the rate of mortality, nor had the diseases supposed to depend on badly-constructed hospitals diminished in number in the new hospital; indeed, Mr. Hawkins had understood that fever had been more prevalent in the new hospital last year than it had ever been in the old one. In his opinion the new hospital was not constructed on the best principles. At the present moment it appeared to him that the Profession as well as the public were running a little too far on the question of statistics of mortality in, as well as on the construction of, hospitals: not that he for one moment meant it to be understood that it was not of the utmost importance that all attention should be paid to the construction and ventilation of hospitals, but it must still be borne in mind that the rate of mortality was not simply a "*brick-and-mortar*" question.

Mr. FERGUSSON said that he thought there was yet much difference of opinion as to the best plan of constructing hospitals. He would be glad, however, to take Mr. Hawkins' word that Queen Charlotte's Hospital was one of the best.

Dr. HICKS, after thanking Dr. Brodie for his valuable paper, said that the mortality of the out-dooor maternity patients, chiefly married, in number 15,000, was 3½ per thousand. Dr. Hicks had not seen a genuine case of puerperal fever. All the cases of what might be included under the name of puerperal fever turned out to be either one of the zymotic diseases, erysipelas or pyæmia. But altogether there had been only twenty-five cases, and of these half died. Students, Dr. Hicks said, who were dissecting, were not allowed to attend women in labour. One student had a case of surgical pyæmia amongst his midwifery patients, and though he attended twenty cases he did not carry infection to the others. There had been no deaths from puerperal mania. Dr. Hicks concluded by asking Mr. Hawkins if, when a patient at the Queen Charlotte's Hospital became ill, a single nurse was kept for that individual patient.

Dr. GRAILY HEWITT believed that in the numerous discussions which had occurred on this general question as to the utility of lying-in hospitals, certain important circumstances had been overlooked. The great mortality occasionally witnessed in lying-in hospitals arose from puerperal fever, disease concerning the nature and prevention of which our knowledge has been, up to within a recent period, comparatively limited; and it was, he believed, to be expected that with the aid of more extended information on the subject the disease in question might be prevented to a very much greater extent than was formerly the case. In the institution with which he was himself connected—the British Lying-in Hospital—the mortality during the thirteen years ending 1861 had been only 0·69 per cent., and during the last two years the number of deaths had been even lower than this. It must be recollected further that a certain number of cases treated in lying-in hospitals were cases of unusual difficulty, and this was to be taken into account in estimating the rate of mortality. He attached the greatest possible importance to isolation of cases one from the other in the prevention of puerperal fever; the atmosphere of one ward should not be allowed to communicate with that of another. So, again, it was essential that the nurses exercise great care, in performing the daily ablutions, not to use sponges or flannels indiscriminately. With reference to puerperal fever, he entirely agreed with the previous speaker in considering that it was not a distinct and separate disease; it was to all intents and purposes pyæmia, and we could only hope for a successful result in its treatment by adopting measures of a sustaining and stimulating character. The mortality in lying-in hospitals from puerperal fever would, he believed, be diminished as the knowledge which has of late years been acquired respecting the nature and treatment of this disease came to be applied.

Dr. F. W. MACKENZIE thought the opinion of the Profession would change as to the advantages of lying-in hospitals. He held that the number of fever cases had nothing to do with the hospital, but with the individuals admitted. If any one, he continued, would study the arrangements of Queen Charlotte's Hospital, comparing it with others, and would consider the nature of the cases admitted, the conclusion arrived at would be that the real cause of the fever case was not in the hospital, but in the patients who were admitted. Patients were admitted who were in a state of starvation, without friends, and with no home. Cases of this kind would die anywhere. Last week, Dr. Mackenzie said, a ballet-dancer was admitted, who died after confinement of a dead and putrid child. She had been seduced. She had then no means of earning her livelihood; was very much exhausted, and in great distress of mind. A case of this kind could not be put down to any supposed defect in the Hospital. The fever, he said, was secondary to some general condition in the patient, and was not in itself a disease to be taken in a hospital by a healthy woman. The whole theory of puerperal fever was wrong.

The AUTHOR, in his reply, said that the registration of the out-patients was not sufficiently accurate for statistical purposes. Those cases of mania ending in recovery were not included in his statement. In reply to Dr. Hicks' query, the Author said that when a patient was taken ill a nurse was taken on for than patient only; and in reply to Dr. Graily Hewitt, he said that the very greatest care was taken as to the sponges.

Dr. WOOD said that at Bethlehem they looked on puerperal mania as the most satisfactory and most curable form of mania.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 12th ult.:—Thomas Edward Blick, Islip, Oxon; Edward Ingram Bostock, Horsham, Sussex; Philip Cowen, Kennington; John Tasker Evans, Hertford; Joseph Fall, York; Charles John Grellet, Lloyd square; Griffith Griffiths, Alltwen, Glamorganshire; Joseph Johnson, Hogsthorpe, Lincolnshire; James M'Cully, Belfast; Henry William Alexander Mackinnon, Somerset street; Robert Edward Owen, Beaumaris; Charles Perks, L.R.C.P., Lichfield; Charles Wightwick Pitt, Malmesbury; Thomas Claye Shaw, Stockport; John Ablewhite Smith, Louth, Lincolnshire; William Westbrook Squires, Liverpool; Timothy Tudge, Yeovil; Joseph Wilkinson Warburton, Liverpool; William Watmough, Pocklington, Yorkshire.

The following gentlemen were admitted Members on the 13th ult.:—Henry Wade Battersby, Dublin; Henry Com-

mins, Bray, Co. Wicklow; Thomas Griffith Evans, Lawrence lane; Alfred Orlando Jones, Barnsbury; John Talfourd Jones, M.B.Lond., Brecon, S. Wales; William Liddard, Mildmay road, Islington; Frederick Manser, Chatham; Thomas Nimmo, Kirkaldy, Fifeshire; John Richard Peel, London; Francis Rawle, Lambeth; George Edward Shuttleworth, Russell place, Fitzroy square.

The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 17th ult., and when eligible will be admitted to the pass examination:—W. H. Ansell, Charing cross; H. H. Braye, Guy's; George Cooper, Leeds School; C. J. S. Digges, Dublin School; R. C. Goddard, Manchester School; F. J. Grose, University College; George Massey, Dublin School; G. B. Millett, St. Mary's; T. C. Murp y, University College; George Percy, Dublin School; H. W. Pullan, Leeds School; Frederick Reynolds, Guy's; Robert Robertson, St. Mary's; William Smith, Manchester School; George Stokes, Dublin School; J. H. Tarleton, St. Bartholomew's; Herbert Wood, Manchester School.

The following gentlemen passed their primary examinations on the 18th ult.:—Edward Borough, Dublin School; John Brady, Belfast; Joseph Burne, Dublin School; William Burrows, Belfast; John Cremonini, Birmingham; W. A. Daniel, St. Bartholomew's; F. F. Dickinson, Dublin School; W. R. G. Hinds, Galway; C. G. Langdon, St. Bartholomew's; R. T. Le Sueur, Edinburgh, R. C. Parkinson, Dublin School; F. T. Prince, St. Bartholomew's; J. H. Rumsey, St. George's; J. N. Stone, Dublin School; Richard Talbot, Guy's; J. E. Tilton, Bristol; R. H. Williams, Dublin School; David Wilson, Belfast.

The following gentlemen were admitted Members on the 24th ult.:—Henry Edward Armstrong, Newcastle; Francis Mears Beckett, Canterbury; Henry Melvill Brewer, Newport, Monmouthshire; Joseph Burne, Dublin; John Foot Churchill, Poole, Dorset; Frederick Fludd Dickenson, M.D., Wicklow; George Cox Douglas, Grantham; Henry Nelson Edwards, Finsbury square; Oliver Humphrey Fowler, Kingsclere, Hants; Augustin Barber Fry, Sleaford; Joseph Gedge, Bexhill, Sussex; William Melville Knipe, Leigh Sinton, Worcestershire; Philip Brookes Mason, Burton-on-Trent; Thomas Richards Phillips, Dublin; Thomas Sanders, Plymouth; William Burt Shorto, Southampton; Edward Roberts Smith, Dudley; Charles James Wills, Stockwell; Andrew Wise, Plumstead, Kent.

At the same meeting of the Court, Mr. Chas. Jas. Devonshire passed his examination for Naval Surgeon. This gentleman had previously been admitted a member of the College, his diploma bearing date April 4th, 1855.

The following gentlemen were admitted Members on the 25th ult.:—Edward Borough, Kilrush, Co. Clare; William Burrows, Liverpool; Matthew Henry Cantrell, Wirksworth; William Cross, M.D., Liverpool; Nicholas Watson Fairles, South Shields; Charles James Fox, L.D.S., Mortimer street, Cavendish square; William Richard Gore Hinds, M.D., Galway; George Levick, Stratford, Essex; William Vacy Lyle, Harrow road; John Norrish, Ceylon; Charles Read, Falmouth; Augustus Morton Roberts, Sheffield; Charles Edward Squarey, Salisbury; William Heath Strange, Streatley, near Reading; Daniel Webster Tomlinson, Penynant, N. Wales.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 19th ult.:—Philip Cowen, Kennington, S.; Francis Albert Davey, Bath; John Arthur Ensor, Carter street, S.; William Nicholas Heygate, Hanslope, Bucks; John Roaf Ireland, Kingswinford, Staffordshire; Evan Jenkins, Cardigan street, S.W.; Charles Durrant Pearless, East Grinstead, Essex; Frederick William Richards, Winchester; Edwin Charles Smallman, Barnet, Herts; Robert Wrentmore Thomas, Cheyne walk, Chelsea; Wm. Warwick Wagstaffe, Walcot place, Kennington; Joseph Wilkinson Warburton, Royal Infirmary, Liverpool; Henry Wilson, Glasgow.

The following gentleman also on the same day passed his first examination:—Richard James Andrews, Guy's Hospital.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their first professional examinations during the May sittings of the Examiners:—William H. Arrowsmith, Dublin; Alexander Clarke, Campsie; William T. Crabbe, Kirriemuir; Frank Kennedy Dickson, Edinburgh: Alexander S. Esson, Edinburgh; G. W. Robertson Hay, Roxburghshire; James Milward, Bristol; Henry Allyne Nicholson, Penrith; Thorburn Paterson, Bonnyrigg; Arthur Strickland Tarbolton, Leeds.

The following gentlemen passed their final examinations, and were admitted L.R.C.P.Edin. and L.R.C.S.Edin.:—John Allen, Malta; James Callaghan, Cork; John Alex. Campbell, Co. Londonderry; Richard Cranke, Lancashire; Smith Houston Davson, Berbice, British Guiana; Evan Jenkins, Llandyssul, Cardigan; George Macdonald, Perthshire; Stephen Coull Mackenzie, Calcutta; John Francis Madigan, Co. Limerick; Matthew Mulvany, Co. Meath; Patrick O'Neill, Co. Kildare; Theobald Andrew Purcell, Dublin; Arthur William Shedden, Madras; William Sinclair, Stirling; Francis M'Bean Stewart, Dundee; John Thomson, Fifeshire.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentleman passed his first professional examinations during the May sittings of the Examiners:—George Haliburton Hume.

The following gentlemen passed their final examinations, and were admitted Licentiates of the College:—George Augustus Christie, New Brunswick; Henry Cook, Newport, Monmouth; William Dobie, Langholm; James Hill, Northumberland; James Johnstone Hyslop Hope, Lanarkshire; John Knox, Tyrone; James George Lyon, Forfar; Angus Macdonald, Aberdeen; John Winspeare McCarty, Cork; Thomas Morris, Fifeshire; Alexander Donald Neil Munro, Edinburgh; Adam Orr, Clonmel; Thomas Raleigh Phayre, Co. Limerick; James Provan, Haddingtonshire; Robert Skimming, Wigtown; James Smith, Dumfries; Parker Arthur Smith, Canada; Archibald Barr Telford, Lanarkshire; William John Wilson, Co. Armagh; John Wyber, Glasgow.

DR. THOMAS CUTLER, OF SPA.—We are requested to state that the report which has lately been circulated in some quarters, of the death of this gentleman, is without foundation, and that he is in perfect health.

PEPSINE FROM THE PANCREAS.—A lecture by Dr. Corvisart contains a hint for the makers of pepsine. The doctor removed the pancreas from a man who died suddenly after inhaling chloroform, cut it into small pieces, and shook them up with 400 grammes of cold distilled water. After filtration, one portion of this liquor was rendered slightly acid with hydrochloric acid; another portion was made alkaline with potash, and the third part was left as it was. The digestive power of each was then tested with fibrin and albumen, the mixture being kept at about 40° C., and in every case the digestion was rapidly effected.

MUNIFICENCE.—The Right Hon. Lord Stanley, M.P., has just transferred to trustees the sum of 1,000*l.* for the benefit of the West Norfolk and Lynn Hospital, and the friends of the undermentioned medical charities will be glad to learn that their respective funds have been increased by the following liberal bequests under the will of Mrs. Elizabeth Veal, of Bellevue, Hampstead, which has just been sworn under 10,000*l.* This lady has directed that 500*l.*, free of duty, be given to University College Hospital, 500*l.* to King's College Hospital, and 500*l.* to the Cancer Hospital. The late Sir William Brown, Bart., of Richmond hill, has bequeathed to the Northern Hospital, Liverpool, 1,000*l.*; the Southern Hospital, 500*l.*; the Royal Infirmary, 500*l.*; Deaf and Dumb School, 500*l.*; Blind School, 500*l.*; and the Eye and Ear Infirmary, 100*l.* Thus we have the magnificent sum of 5,600*l.* distributed to medical charities in one week.

APPOINTMENT OF EXAMINER AT THE ARMY MEDICAL BOARD.—Mr. Paget, after holding the post of Examiner in Surgery to the East India Company, and then to the Army Medical Department for ten years, has resigned the appointment. The Secretary of State, at the suggestion of the Director-General, has appointed Mr. Prescott Hewett, of St. George's, as the successor to Mr. Paget.

ROYAL COLLEGE OF PHYSICIANS.—The President and Fellows of the Royal College of Physicians have issued invitations to a *conversazione*, to take place at the College, on Saturday, June 18th, at 9 o'clock P.M.

DEATH.

COOLEY.—On the 17th ult., in St. John street road, E.C., after a very protracted illness, at the age of 48, Mrs. Mary Ann Cooley (*née* Wills), the beloved wife of Mr. Arnold J. Cooley, a gentleman for many years connected with the chemical department of this Journal.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JUNE 1.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Obstetrical Society of London, 8 p.m.—Dr. Greenhalgh, "On Placenta Prævia."—Dr. Aveling, "On Immediate Transfusion."

THURSDAY, JUNE 2.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; Great Northern Hospital, King's cross, 2 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopœdic Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Hullah "On Music (1600—1750);" Chemical Society, 8 p.m.—Prof. Stokes, "On the Discrimination of Organic Bodies by their Optical Properties."

FRIDAY, JUNE 3.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal Institution, 8 p.m.—Prof. Frankland, "On Recent Chemical Researches in the Royal Institution."

SATURDAY, JUNE 4.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Alexander Herschel, "On Falling Stars and Meteorolites."

MONDAY, MAY 6.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JUNE 7.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

THE OBSTETRICAL SOCIETY.—The notice has been received.

THE HARVEIAN SOCIETY.—The report has been received, and will be inserted next week.

THE ROYAL SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS.—The report has been received, and the subject shall be noticed.

A YOUNG PRACTITIONER.—The letter is inserted.

A CANDIDATE.—At the institution in question, the candidate is examined in histological anatomy, and he is required to describe specimens exhibited by the microscope.

DR. R. B.—We recommend you to be very cautious in purchasing a practice, and to take the advice of some respectable agent before you take the step.

JUVENIS.—We must decline to inform you how a medical diploma can be obtained without residence or examination, because such a document would be practically worthless to the possessor. The traffic in degrees is altogether disgraceful both to the sellers and the buyers.

DR. H.—The letter has been received.

DR. S. M.—We regret that we were unable to avail ourselves of the ticket so kindly forwarded to us.

DR. CUTLER.—The subject is noticed in another column.

M. S. W. shall receive a private note.

DR. PITMAN'S letter is inserted.

Anatomy, Physiology, Pathology, and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland Place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

The Medical Baths and Fumigations.

40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible, or have altogether failed in effect. Imitations having arisen, be particular in the address.

DINNEFORD'S

Pure Fluid Magnesia, now perfect in purity and strength.

"Mr. Dinneford's Solution may fairly b taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.,) specially adapted for the use of Medical Men and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

Mr. Howard, Surgeon Dentist,

52 FLEET STREET,

has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble natural teeth as not to be distinguished from the original by the closest observer, they will never CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does NOT REQUIRE the EXTRACTION of ROOTS, or any PAINFUL OPERATION, and will support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication. Decayed teeth stopped, and rendered sound and useful in mastication.—52 FLEET STREET. At home from Ten till Five.

MAKERS TO THE QUEEN AND PRINCE OF WALES

FRY'S | HOMŒPATHIC ICELAND MOSS PEARL | **COCOA.**

FRY'S SOLUBLE CHOCOLATE.

FRY'S CHOCOLATE for Eating in sticks and drops.

The superior quality of J. S. FRY and SONS' Articles has been attested by uniform public approbation during a century.

They are the ONLY English house in the trade to whom a PRIZE MEDAL was awarded 1862.

Lichen Islandicus, or Iceland Moss COCOA.

Strongly recommended by the Faculty.

See Testimonials of Dr. Hassall, Dr. Normandy, with others To be had everywhere, at 1s. 4d. per lb.

Manufactured by

DUNN AND HEWITT, LONDON.

Weiss's Illustrated Catalogue, containing nearly 800 Engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price 5s.

62 Strand, London.

"This Catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced; and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour, which we are glad to see strictly observed in this Catalogue."—Vide 'The Lancet,' Sept 12th, 1863.

Lithographic Printing by Steam.—J. CROSS and SON execute in a superior style, on very moderate terms, every description of Commercial Lithography, Steel, and Copperplate Engraving and Printing. Contracts with large consumers. Wedding and Visiting Cards, Invitation Notes, Envelopes, and every description of Fancy Stationery.—J. CROSS and SON, Lithographers, Engravers, Steam-machine Printers, and Stationers, 18 Holborn hill, E.C.

Established 1813.—Works, Baldwin's gardens.

The "Dyer" Telescope, 12 inch, three draws, in case, with sling, 10s. 6d.

THE "CORPORATION" TELESCOPE, 18 inch, three draws, bronzed, in case, with sling, 25s.

THE "EXHIBITION BINOCULAR" GLASS, in case, with sling, 21s.

Manufactured and sold by E. G. WOOD, Optician &c., 74, Cheapside, London.

Illustrated list free by post on receipt of postage stamp.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

BY J. LUMLEY EARLE, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 344.)

The Remedies.

In the employment of cold, we should bear in mind the following facts—that cold, applied for too lengthened a period, acts as a depressant, and loses its effect; that the colder the water, the greater the shock, and the more powerful is its effect in inducing permanent uterine contraction. We learn from them that, in bad cases, the continued application of cold requires care lest it increase the exhaustion; that it is most important to have the water as cold as it can be obtained, as the effect depends upon the coldness, and not upon the quantity of water used. Water, fresh from the pump, is generally sufficient; if we can obtain ice easily, so much the better. Dr. Tyler Smith recommends in some instances the application of cold and warm water alternately. I should say it would be most useful in cases where cold water had been applied for some time, and was losing its efficacy.

Ergot.—When good in quality, ergot is a most valuable remedy; it arrests the flooding chiefly by exciting contraction of the uterus. One fault in the drug is, that it sometimes fails in producing its specific effect. The failure may be due to the ergot being inert, or to some peculiarity of the patient rendering her insusceptible to its action. It very rarely fails from an idiosyncrasy, but from the absence of the active principle (whatever that may be) of the ergot. There is great difficulty, first, in getting good ergot, and next in keeping it good. Prior to the purchasing of the drug, we should examine its quality. The grains of ergot are from half an inch to an inch and a half in length, of a dark purple or black exterior, and ribbed in the longitudinal direction. On its surface, longitudinal and transverse fissures are generally present. On breaking a grain across, the interior is either of a white colour tinged with purple, or of a dirty yellow hue. The difference of colour depends probably upon the age of the grain. Ergot has also a very strong peculiar odour, irritating to the nose. The best indications of good ergot are the large size of the grains, both in length and breadth, and the strong oppressive odour. Good powdered ergot is known by its not being as fine as dust, and by its possessing the odour in a strong degree. The insect which feeds upon it, and destroys it, is a species of acarus, and may be seen sometimes by the naked eye, although its form cannot be defined without the aid of a microscope. These creatures will, in a very short time, reduce coarsely-powdered ergot to a fine dust, and render it perfectly inert. The best way to prevent ergot from spoiling is to keep it in the form of grain in a glass stoppered bottle, with a piece of camphor about the size of a pigeon's egg thrust into the centre of the mass. If a cork instead of a glass stopper be used, the acari will soon riddle it through, and allow free ingress of air. Not more than an ounce or two of ergot ought to be crushed for use, as it rapidly deteriorates in the powdered state. It is given in the form of infusion. One drachm, or a good tea-spoonful, is placed in a teacup of *boiling* water, and allowed to stand ten minutes, when half the quantity may be administered, and the other half in twenty minutes or half an hour after, if the desired result should not have been produced. Before taken, the infusion should be stirred up, that the patient may swallow the ergot grounds as well as the fluid. Besides the infusion, there are other fluid preparations, and an extract called ergotine. I have used the latter, and one of the former, and the results have prejudiced me against their use. In some cases, uterine contraction followed apparently their employment; while in others no effect at all was produced. I could not depend upon them as I could upon the infusion of good ergot. One great objection to them is, that we cannot be certain that they are made from ergot of good quality. I have lately heard the extractum ergotæ liquidum, B.P., very highly spoken of, and I intend to give it a trial. The dose is one tea-spoonful. A trustworthy fluid preparation of ergot would be of manifest advantage. The active principle would be preserved from the ravages of the acari, and it would be ready for immediate use—a point of considerable importance in an urgency like flooding. Although ergot is about one of the most valuable remedies we possess in the treatment of post-partum hæmorrhage, there are cases in which no good will be attained by its administration, and others in which it will do harm. I shall particularise them in a subsequent communication.

The Introduction of the Hand into the Uterine Cavity.—This is one of the means of arresting hæmorrhage which requires care and judgment in its use. I do not agree with the opinion of many writers that it should be put into a practice only as "a last resource." I have in several cases made use of it as a first remedy, and in a few moments, by so doing, have placed patients from a state of imminent danger into that of comparative safety. The ease or difficulty with which the hand may be passed into the uterus depends very much upon the size of the hand. We know what a slight difference in the size of an infant's head, or of the pelvic cavity will make the labour easy or difficult; and just so in the introduction of the hand. If a medical man has a very large hand, and his fingers are all thumbs, he will find great difficulty in passing his hand into the uterus, and will cause his patient great suffering; but if his hand be small, it will pass easily and give very little pain. I have noticed, and it is what we would expect, that the men who deprecate the procedure are generally those who possess big hands. The effect upon the patient will also depend a great deal on the size of the hand. The smaller it is, the easier it will pass, the less pain it will cause, and the less shock and exhaustion will ensue. Let it not be thought from the above remarks that I look upon the introduction of the hand as a light matter, to be undertaken indiscriminately without any reference to the case before us, for I do not; I never pass my hand into the uterus unless I have a good reason for it: but if, from the nature of the case, I feel satisfied that that is the correct proceeding, I do not hesitate, and go on trying a number of other remedies with the hope that the introduction of the hand may be avoided. Such hesitation, in some cases, would prove fatal. Dr. Tyler Smith says:—"I believe, in the present day, more mischief is caused from a kind of fear of the uterus, and of interfering with its natural action, than from bold and intelligent efforts to guide and control it."

The introduction of the hand may be necessary for the application of internal pressure and irritation, or for the removal of substances which keep up the flooding by distending the cavity of the uterus, and preventing its due contraction. Before it is undertaken, brandy should be given to the patient, and the nurse told to continue its administration from the time that the hand commences to pass through the vulva until it is removed. In flooding cases, this precaution should never be omitted. It averts the faintness and shock which otherwise might ensue, and it also assists in drawing away the patient's attention from what is being done. Since I have taken the precaution of having brandy given *during* the operation, I have not observed the slightest depression or fainting result.

The hand may be introduced as follows:—If the patient is lying on her left side, the left arm and hand will be more readily passed than the right. They should be well greased, and the fingers and thumb so packed as to be made to occupy as small a space as possible. The first and fourth fingers should be placed in front of the second and third and the tip of the thumb, at the base of the cleft between the third and fourth finger. The usual plan of placing the tips of the fingers and thumb together is not so good, as it

takes up more room. The hand should be then passed gently and slowly, feeling the way as one goes on through the vulva and vagina into the uterus. The hand, as it passes through the vulva, generally produces more or less pain on account of the soft parts being pinched against the descending rami of the pubis. The mere presence of the hand in the vagina or uterus does not give rise to much pain. It frightens more than it hurts the patient. The hand should never be removed until it has effected the purpose for which it was passed; for instance, in adherent placenta, to pass the hand into the uterus, and then to take it away again without bringing away the placenta, on account of the patient's or friend's entreaties, would show a great want of presence of mind, and it would be acting cruelly instead of kindly to the patient, because the introduction of the hand would have to be repeated. I shall postpone the description of what has to be done with the hand while in the cavity of the uterus until I come to consider the causes for the removal of which it has to be passed.

In a very bad case, where the patient is exceedingly low, it may be a question as to whether the hand should be passed into the uterus before the patient has somewhat rallied. The cases are quite exceptional, in which it would be well to wait. If a great loss of blood is going on, we cannot expect that the patient's condition will improve, but just the reverse; and if the hand has to be passed at all, the sooner it be done the better. During the operation, in these cases of great depression, the brandy must be poured down the patient's throat undiluted with water. The introduction of the hand, and especially whatever it has to do in the uterus, should be done gently and deliberately.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XVII.

The compounds of silver require but a very short notice. There are but two, the nitrate and oxide, and the directions for the preparation of these might as well have been omitted from the Pharmacopœia.

In Appendix A we notice Refined Silver, pure metallic silver, from which the above-named compounds are to be prepared. Ammonia added in excess to a solution of the metal in nitric acid should give a clear solution, without colour. The ordinary impurities in silver are copper and lead: if the former is present, the ammoniacal solution will have a blue colour, and if lead was present in the silver, the solution will be turbid, in consequence of the precipitation of the hydrated oxide of lead, or a basic nitrate, according as the excess of ammonia employed in the experiment is large or small.

ARGENTI NITRAS.—This salt is to be prepared by dissolving refined silver in diluted nitric acid with the aid of heat. In this operation some nitric acid is decomposed to oxidize the silver, and the remainder combines with the oxide to form the nitrate of silver. These changes are represented by the following equation:—

$$3\,Ag + 4\,NO_5 = 3\,AgO,\,NO_5 + NO_2.$$

It is hardly necessary to say that the operation should be conducted under a chimney or in the open air, to avoid any annoyance from the red fumes of nitrous acid which are formed as soon as the binoxide of nitrogen comes in contact with the atmosphere.

The solution of the nitrate thus obtained is to be evaporated, and set aside to crystallize.

We have before had occasion to remark, that those who defend the introduction of such processes as the above into the Pharmacopœia do so on the ground that these directions are intended for the instruction of medical men or pharmaceutists who may be distant from any source of supply, and may want to prepare the salts for themselves. If this is the intention, it would be better to give directions for the employment of materials which are likely to be at hand. Pure metallic silver is a scarce article; but silver coin is to be found all over the world. Silver coin, however, always contains copper; and it may be useful to our readers to know a means of preparing pure nitrate of silver when coin is employed in place of pure silver.

In the first place, we may mention that pure silver can be easily obtained from the nitric solution of the coin by diluting it with water, and precipitating the silver by means of metallic copper. This precipitated silver, after having been well washed with water to remove all traces of nitrate of copper, can be again dissolved in nitric acid, to form pure nitrate of silver.

Another and simpler method, but one which requires a little careful manipulation, is the following:—The nitric solution of the coin is evaporated to dryness in a porcelain dish, and then the heat is increased nearly to redness. At this point the nitrate of silver merely fuses, but nitrate of copper is decomposed, nitrous acid and oxygen are evolved, and black oxide of copper is left behind. The heat must be continued for some time, and a portion of the fused mass must be occasionally removed, dissolved in water, the solution filtered, and tested with excess of ammonia. When a blue colour is no longer produced, it shows that all the nitrate of copper has been decomposed, and the mass may then be allowed to cool. It is now treated with water, and the solution separated from the oxide of copper will, on evaporation, give pure nitrate of silver.

Nitrate of silver crystallizes "in colourless tabular right-rhombic prisms," which are anhydrous; but the form in which medical men most often see it is that of cylindrical rods, which are made by fusing the crystals and pouring the liquified salt into moulds. In this state it is liable to adulteration, and the common adulterant is nitrate of potash. The Pharmacopœia test of purity is the quantitative determination of the silver in the form of chloride. Ten grains dissolved in a small quantity of distilled water, and precipitated with hydrochloric acid, should give 8·44 grains of the chloride; and the solution filtered from the precipitate should leave no residue on evaporation. Potash would not be precipitated by the hydrochloric acid, and if present in the filtered solution chloride of potassium would be left as a residue on evaporation. Lead, if present, will be found in the way to be presently described.

Sticks of nitrate of silver are very brittle, which makes it difficult to point them for use as a caustic. Other substances are, therefore, sometimes fused with the crystals to give toughness to the sticks. The least objectionable of these is chloride of silver, which will be recognised by its insolubility in water. But nitrate of lead is sometimes employed for the same purpose, and this admixture, unless it is fairly acknowledged on the label, will constitute a serious adulteration. It may be detected in the following way:—Hydrochloric acid is added to a solution of the suspected stick; the chlorides of silver and lead will be precipitated together, but on boiling the precipitate with a considerable amount of water the chloride of lead will be dissolved, and the lead will be detected in the filtered solution by the addition of dilute sulphuric acid, which will throw down sulphate of lead.

ARGENTI OXIDUM.—The Pharmacopœia orders oxide of silver to be precipitated from a solution of the nitrate by means of lime water. This is the process of the Dublin Pharmacopœia, but the precipitant always employed by makers of the oxide is a solution of potash. In either case the result is the same, an olive-brown powder, slightly soluble in water, and freely soluble in ammonia. It is also soluble in nitric acid, and this solution should have all the characters of the nitric solution just described. When heated to redness the oxide parts with its oxygen, and metallic silver is left behind. Twenty-nine grains of the oxide should leave twenty-seven grains of silver.

RESTORATION OF THE APPARENTLY DEAD FROM DROWNING.

The following important Instructions for the Restoration of the Apparently Dead from Drowning are the result of very extensive inquiries recently made by the Royal National Life-boat Institution amongst medical men, medical bodies, and coroners throughout the United Kingdom.

The Lords Commissioners of the Admiralty have ordered 1,000 of these important directions to be circulated throughout Her Majesty's Fleet; and the Commodore Controller-General of the Coast-guard has also requested that 2,000 of the directions should be distributed throughout the Coast-guard Service. They have also been forwarded to our colonies and to foreign countries.

The accompanying illustrations cannot fail to make the instructions perfectly intelligible to everyone; and in issuing them the National Life-boat Institution is entitled to the additional gratitude of the community.

I.

Send immediately for medical assistance, blankets, and dry clothing; but proceed to treat the patient *instantly* on the spot, in the open air, with the face downwards, whether on shore or afloat, exposing the face, neck, and chest to the wind, except in severe weather, and removing all tight clothing from the neck and chest, especially the braces.

The points to be aimed at are—first and *immediately*, the *restoration of breathing;* and, secondly, after breathing is restored, the *promotion of warmth and circulation.*

The efforts to *restore breathing* must be commenced immediately and energetically, and persevered in for one or two hours, or until a medical man has pronounced that life is extinct. Efforts to promote *warmth* and *circulation*, beyond removing the wet clothes and drying the skin, must not be made until the first appearance of natural breathing; for if circulation of the blood be induced before breathing has recommenced, the restoration to life will be endangered.

FIG. 1.—INSPIRATION.

FIG. 2.—EXPIRATION.

Figs. 1 and 2.—To illustrate the position of the body during the employment of Dr. Marshall Hall's Method of Inducing Respiration.

II.—TO RESTORE BREATHING.

To clear the Throat.—Place the patient on the floor or ground with the face downwards, and one of the arms under the forehead, in which position all fluids will more readily escape by the mouth, and the tongue itself will fall forward, leaving the entrance into the windpipe free. Assist this operation by wiping and cleansing the mouth.

If satisfactory breathing commences, use the treatment described below to promote warmth. If there be only slight breathing, or no breathing, or if the breathing fail, then—

To excite Breathing.—Turn the patient well and instantly on the side, supporting the head, and excite the nostrils with snuff, hartshorn, and smelling-salts, or tickle the

throat with a feather, &c., if they are at hand. Rub the chest and face warm, and dash cold water, or cold and hot water alternately, on them.

If there be no success, lose not a moment, but instantly—

To imitate Breathing.—Replace the patient on the face, raising and supporting the chest well on a folded coat or other article of dress.

Turn the body very gently on the side and a little beyond, and then briskly on the face, back again; repeating these measures cautiously, efficiently, and perseveringly about fifteen times in the minute, or once every four or five seconds, occasionally varying the side. (*By placing the patient on the chest, the weight of the body forces the air out; when turned on the side, this pressure is removed, and air enters the chest.*)

On each occasion that the body is replaced on the face, make uniform but efficient pressure, with brisk movement, on the back between and below the shoulder-blades or bones on each side, removing the pressure immediately before turning the body on the side. During the whole of the operations let one person attend solely to the movements of the head and of the arm placed under it. (*The first measure increases the expiration, the second commences inspiration.*)

*** The result is respiration or natural breathing; and if not too late, life.

Whilst the above operations are being proceeded with, dry the hands and feet; and as soon as dry clothing or blankets can be procured, strip the body and cover or gradually reclothe it, but taking care not to interfere with the efforts to restore breathing.

III.

Should these efforts not prove successful in the course of from two to five minutes, proceed to imitate breathing by Dr. Silvester's method, as follows:—

Place the patient on the back on a flat surface, inclined a little upwards from the feet; raise and support the head and shoulders on a small firm cushion or folded article of dress placed under the shoulder-blades.

Draw forward the patient's tongue, and keep it projecting beyond the lips: an elastic band over the tongue and under the chin will answer this purpose, or a piece of string or tape may be tied round them, or by raising the lower jaw the teeth may be made to retain the tongue in that position.

FIG. 3.—INSPIRATION.

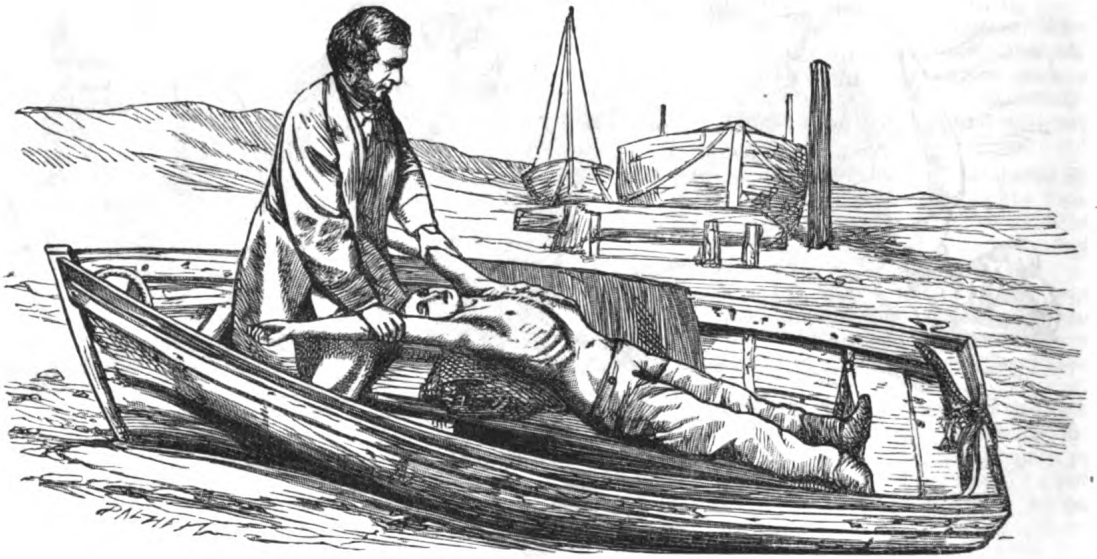


FIG. 4.—EXPIRATION.

Figs. 3 and 4.—To illustrate the position of the body during the employment of Dr. Silvester's Method of Inducing Respiration.

Remove all tight clothing from about the neck and chest, especially the braces.

To imitate the Movements of Breathing.—Standing at the patient's head, grasp the arms just above the elbows, and draw the arms gently and steadily upwards above the head, and *keep them stretched* upwards for two seconds. (*By this means air is drawn into the lungs.*) Then turn down the patient's arms, and press them gently and firmly for two seconds against the sides of the chest. (*By this means air is pressed out of the lungs.*)

Repeat these measures alternately, deliberately, and perseveringly, about fifteen times in a minute, until a spontaneous effort to respire is perceived, immediately upon which cease to imitate the movements of breathing, and proceed to *induce circulation and warmth.*

IV.—TREATMENT AFTER NATURAL BREATHING HAS BEEN RESTORED.

To promote Warmth and Circulation.—Commence rubbing the limbs upwards, with firm grasping pressure and energy, using handkerchiefs, flannels, &c. (*By this measure the blood is propelled along the veins towards the heart.*)

The friction must be continued under the blanket or over the dry clothing.

Promote the warmth of the body by the application of hot flannels, bottles, or bladders of hot water, heated bricks, &c., to the pit of the stomach, the arm pits, between the thighs, and to the soles of the feet.

If the patient has been carried to a house after respiration has been restored, be careful to let the air play freely about the room.

On the restoration of life, a tea-spoonful of warm water should be given; and then if the power of swallowing have returned, small quantities of wine, warm brandy-and-water, or coffee, should be administered. The patient should be kept in bed, and a disposition to sleep encouraged.

GENERAL OBSERVATIONS.

The above treatment should be persevered in for some hours, as it is an erroneous opinion that persons are irrecoverable because life does not soon make its appearance, persons having been restored after persevering for many hours.

APPEARANCES WHICH GENERALLY ACCOMPANY DEATH.

Breathing and the heart's action cease entirely; the eyelids are generally half-closed; the pupils dilated; the jaws clenched; the fingers semi-contracted; the tongue approaches to the under edges of the lips, and these, as well as the nostrils, are covered with a frothy mucus. Coldness and pallor of surface increase.

CAUTIONS.

Prevent unnecessary crowding of persons round the body, especially if in an apartment.

Avoid rough usage, and do not allow the body to remain on the back unless the tongue is secured.

Under no circumstances hold the body up by the feet.

On no account place the body in a warm bath, unless under medical direction, and even then it should only be employed as a momentary excitant.

By order of the Committee,
RICHARD LEWIS, Secretary.

Royal National Life-boat Institution,
London, May, 1864.

SOIREE AT UNIVERSITY COLLEGE.—On Wednesday last, the Professors of University College threw open the spacious rooms of this institution, including the Library, the Flaxman Gallery, and the extensive museums of anatomy, comparative anatomy, and pathology, for a *conversazione.* A number of interesting objects were displayed, as paintings, philosophical and surgical instruments, and other articles of science and *vertu*; and there was a numerous attendance of professors, students, former pupils and friends of the College, and of the literary and scientific world. These *réunions* are among the most pleasant meetings of the season.

REVIEW OF BOOKS.

Lectures on the Elements of Comparative Anatomy. By Thomas Henry Huxley, F.R.S., Professor of Natural History, Royal School of Mines; and Professor of Comparative Anatomy and Physiology to the Royal College of Surgeons of England. *On the Classification of Animals and on the Vertebrate Skull.* 8vo. pp. xi. and 303. London, 1864.

Handbuch der Zoologie. Von Wilh. C. H. Peters, Prof. der Zoologie und Director des Kön. Zoolog. Museums in Berlin; Jul. Victor Carus, Prof. der vergleichenden Anatomie in Leipzig; und C. E. Adolph Gerstaecker, Docent der Zoologie an der Universität zu Berlin. Zweiter Band. *Arthropoden*, bearbeitet von A. Gerstaecker. Pp. 642. Leipzig, 1863.

(*Manual of Zoology.* By Wilhelm C. H. Peters, Professor of Zoology and Director of the Royal Zoological Museum of Berlin; Julius Victor Carus, Professor of Comparative Anatomy at Leipsic; and C. E. Adolph Gerstäcker, Teacher of Zoology in the University of Berlin. Second volume, Arthropoden. Edited by A. Gerstäcker. Pp. 642. Leipsic, 1863.)

Professor Huxley's work contains, substantially, the lectures which he delivered, in the spring of 1863, at the Royal College of Surgeons, in discharge of his duty as Hunterian Professor of Comparative Anatomy and Physiology. He purposes, as we are glad to learn from his preface, to publish the substance of subsequent courses in a similar manner; and by that process to bring out, eventually, a comprehensive, though condensed, systematic work on comparative anatomy. "In *intention*, therefore," he adds, "the work now before the reader is the first of a series, to be followed in due order by a second 'On Man and the other Primates;' a third, 'On the Remaining *Mammalia*;' and so on." While we heartily trust that the learned Professor will be enabled to bring this gigantic scheme to a successful issue, and that we may live to review his concluding volume, we cannot help feeling, when thinking of Buckle, Macaulay, and many others we could name, how comparatively seldom it is that really great writers are allowed to carry out the plans they have devised for themselves in the vigorous and ambitious period of their manhood. But even if our evil forebodings should turn out true, each volume, as it appears, will treat of a special subject, and will be, both in form and matter, independent of the rest.

Of the fourteen lectures contained in the present volume, the first six are devoted to "The Classification of Animals," while the last eight treat of "The Vertebrate Skull." To enter with any detail into a notice of that portion of the work which treats of such points as the skulls of fishes, amphibia, reptiles, birds, and mammals, the comparison of their skulls structurally and developmentally with that of man, and the theory of the vertebrate skull, would require us to go more deeply into the apparent mysteries of transcendental anatomy than the great majority of the readers of the MEDICAL CIRCULAR would feel inclined to follow; and we shall, therefore, confine our remarks to the important subject of Classification.

After a few words on the importance and value of morphological classification, he observes, that "the first point is to ascertain whether any—and if so, what—groups of animals can be established, the members of which shall be at once united together and separated from those of all other groups by well-defined structural characters." Beginning at the lowest point of the animal scale, he describes briefly but clearly the GREGARINIDA, extremely simple microscopical organisms closely resembling an ovum, and inhabiting for the most part the bodies of invertebrate animals (the common earthworm, for example), and the RHIZOPODA, some of which are even simpler in their organization than the *Gregarinida.* "In these lowest forms of animal life there is absolutely nothing worthy of the name of organization to be discovered by the microscopist. In the substance of many of these creatures there is nothing to be discerned but a mass of jelly, which might be represented by a little particle of

thin glue: not that it corresponds with the latter in composition, but it has that texture and sort of aspect; it is structureless and organless, and without definitely-formed parts. Nevertheless, it possesses all the essential properties and characters of vitality; it is produced from a body like itself; it is capable of assimilating nourishment and of exerting movements—nay, more, it can produce a shell, a structure in many cases of extraordinary complexity and most singular beauty." Those of our readers who have seen Dr. Carpenter's recent work 'On the Foraminifera' (published by the Ray Society) will fully acquiesce in the truth of Professor Huxley's remark concerning the complexity and beauty of the shell. The SPONGIDA are next considered, and their true animal nature distinctly pointed out; and the first lecture concludes with the INFUSORIA—"and here again, within the last few years, prodigious strides have been made in our knowledge of the subject. Although the *Infusoria* have been favourite studies for many years, still, it is only quite recently that the cycle of life of these animals has been made almost completely known, and that we have become acquainted with the true sexual process as it occurs in them." Of this group the *Paramœcium* (a very common genus) is taken as a typical example, and its form, structure, and various modes of propagation are well described. The parts formerly termed the "nucleus" and "nucleolus" are now known to be the ovary and the testis.

The second lecture includes the description of animal forms, regarding which our general knowledge is far greater and more certain than is the case of the groups as yet mentioned: it treats of the HYDROZOA (comprising the Hydroid Polypes and the *Medusæ* or jelly-fish), the ACTINOZOA (the sea-anemones, coral-polypes, &c.), the POLYZOA (such as *Flustra* or the sea-mat, *Plumatella*, &c.), the BRACHIOPODA (whose internal structure is well shown by a diagram of *Waldheimia australis*, copied from a figure given by Hancock in his memoir on these animals in the 'Philosophical Transactions' for 1857), the ASCIDIOIDA, (remarkable, amongst other things, for possessing a heart which periodically (usually after about twenty minutes) reverses the direction of its contractions, so that its two ends (for it is merely an open muscular tube) are alternately arterial and venous; the LAMELLIBRANCHIATA (including mussels, cockles, oysters, and all the fabricators of what are commonly known as bivalve shells, except the *Brachiopoda*); the BRANCHIOGASTEROPODA, (a group which includes the whelks, periwinkles, sea-slugs, and, in short, such of the *Gasteropoda* of Cuvier as breathe water either by means of the thin wall of the mantle cavity, by special pallial branchiæ (*Pectinibranchiata*, *Tectibranchiata*, &c.), or by certain parts of the integument of the body (*Nudibranchiata*), more or less specially modified, and whose distinguishing characters are—1. The invariable presence in the mouth of an organ which is usually, though not very properly, called the tongue, and for which Professor Huxley suggests the more appropriate name of *odontophore*. "It consists essentially of a cartilaginous cushion, supporting, as on a pulley, an elastic strap, which bears a long series of transversely-disposed teeth. The ends of the strap are connected with muscles attached to the upper and lower surface of the hinder extremities of the cartilaginous cushions; and these muscles, by their alternate contractions, cause the toothed strap to work backwards and forwards over the end of the pulley formed by its anterior end. The strap consequently acts after the fashion of a chain-saw upon any substance to which it is applied, and the resulting wear and tear of its anterior teeth are made good by the incessant development of new teeth in the secreting sac in which the hinder end of the strap is lodged. Besides the chain-saw-like motion of the strap, the odontophore may be capable of a licking or scraping action as a whole." 2. The primary bend of the alimentary canal is always to the hæmal or heart side of the body, instead of the neural side;) the PULMOGASTEROPODA (which are the Pulmonate *Gasteropoda* of Cuvier, the snails and slugs, and agree with the preceding group in most points, excepting in the essential one of their breathing air instead of water, and in the direction of the primary bend of the intestine, which points to the neural side of the body; the question of the neural flexure of the intestine is, however, one which requires further investigation;) and the PTEROPODA and CEPHALOPODA, in both of which groups there is an odontophore constructed upon the principle already described.

(To be continued.)

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. ERNEST HART commences the number with a clinical lecture "On Cataract, with Reference to Improved Methods of Diagnosis and Treatment." He states that all his recent experience confirms his preference for extraction as the best method for removing cataract; and even in the case of young children, the operation by solution is less applicable than it was once supposed to be. Reclination is altogether condemned by Mr. Hart. The operation of extraction by the flap is then described, the performance of iridectomy being sometimes required as a preliminary or associated proceeding in certain exceptional cases. There is another mode of removing cataract which Mr. Hart has practised successfully—namely, by linear extraction; the incision being made in the upper or external part of the cornea, the capsule being incised, and the fluid cataract being allowed to pass out by the wound. The word *fluid* is placed before cataract because it is only in cases of fluid cataract that this operation is admissible, and care must be taken to learn beforehand the character, structure, and consistence of the cataract, by direct ophthalmoscopic and oblique illumination. Linear extraction, in cases where it can be performed, is far less dangerous than the flap operation. ——Dr. JOHN CHAPMAN, in a paper "On Vaso-Motor Therapeutics," describes the practice which he adopts of applying alternately ice and warmth to the vicinity of the spinal cord, in cases of epilepsy, paralysis, and uterine diseases, and he explains the theory on which his practice is founded. His reasoning is exceedingly abstruse, and his views appear at first sight to be paradoxical, but they are very ingenious, and are worked out with great care. The leading idea is derived from the discovery that the sympathethic system of nerves causes the contraction and permits the dilatation of blood-vessels; and Dr. Chapman argues that the application of heat and cold to the spine causes these changes in the blood-vessels, through the influence of the nervous filaments distributed over their coats. In opposition to received views, Dr. Chapman maintains that the application of cold expands the blood-vessels, and that heat contracts them.——Dr. G. M. HUMPHRY, of Cambridge, in continuing his "Surgical Observations," describes the difficulties and varieties met with in the operation for lithotomy, in which he has had a large experience. He gives a decided preference to lithotomy over lithotrity in the greater number of cases which have come under his care, although he admits that there are some instances, generally among the upper classes, in which the latter operation is preferable.——Mr. THOMAS LANGSTON relates a short "Case of Sudden Delivery," the

patient being a single woman, who was delivered in the street, while she was walking to a friend's house. The umbilical cord was torn, and the head of the child was contused by its fall on the pavement.

The 'Medical Times and Gazette.'

Dr. George Harley continues his lectures "On the Urine and Diseases of the Urinary Organs," his present subject being uric acid. This acid is the most common ingredient of all calculi; and of a hundred and twenty-six calculi in the museum of University College, analyzed by Dr. Harley, eighty-seven consisted of this acid either in whole or in part. In the medical treatment of calculus, all the alkaline carbonates are useful except that of ammonia, the urate of ammonia being much less soluble than the others. In administering the alkalies, it is not necessary to do more than to render the urine neutral, for when it becomes artificially alkaline, the triple phosphate may be deposited in place of the uric acid. Dr. Harley coincides in the opinion generally entertained, that gout and rheumatism are caused by the presence of an abnormal amount of acid in the system—probably uric acid in the first and lactic acid in the second.——Mr. John Wood concludes his papers "On the Radical Cure of Inguinal Rupture," by pointing out the class of cases which are best adapted for this operation. He states that after the age of fifty the proceeding is not advisable; that in women it is seldom necessary; but that it is very successful in children and in boys under fourteen years of age.——Dr. W. Murray contributes a paper "On the Administration of Chloroform in Cases of Epilepsy and Chorea," and describes two cases, one of each disease, in which this agent was employed. In the case of chorea, the result was fatal, although the chloroform appeared to act beneficially; in the case of epilepsy, which was that of a man of sixty-nine, the chloroform was decidedly serviceable in controlling the attacks. It was inhaled in doses of ten drops from a linen cloth three times a-day, and the result seems to have been a complete recovery in about nine weeks.

THE MEDICAL COUNCIL AND THE BRITISH PHARMACOPŒIA.

The following discussion on the British Pharmacopœia took place at the last meeting of the Medical Council, and presents some points of interest:—

Dr. Alex. Wood wished to know if any opportunity would be given for discussing the report of the Pharmacopœia Committee which was adopted at the rising of the Council on Saturday. Not that he was one of those who condemned the Pharmacopœia, but a great deal of undeserved comment had been passed upon it, and he thought it absolutely essential that there should be some discussion upon the Pharmacopœia itself.

The President suggested that the proper time would be when the payments on account of the Pharmacopœia came up for consideration.

Dr. Quain moved that the committee should consist of four members and the President. The committee was intended for supervision, not for work; therefore the more limited and the more restricted it was the better. It was proposed that it should consist of one member for Scotland, one for Ireland, and two for England. The duty of the committee would be to draw up a plan as to the extent to which the present Pharmacopœia should receive modifications; he hoped they would not be very great or very material. It would be their endeavour to find one or two editors to whom the task of revising the work would be assigned, under the supervision of the committee; and before it was printed it would be finally submitted to the Council for further suggestion or alteration, so that the Pharmacopœia should go forth as a national work, with the impress of the highest authority upon it. He nominated Dr. Christison for Scotland, Dr. Apjohn for Ireland, and Dr. Sharpey and himself for England, it having been suggested that, as he had taken an active part in the matter, he should be one of the committee.

Mr. Syme seconded the motion.

Dr. Sharpey said he had long ceased to take much practical interest in the Pharmacopœia, but if the Council thought he could really be of service he should be happy to give his time and trouble.

Dr. Christison reminded the Council that last year he undertook charge of the changes and improvements that are taking place in the processes of pharmacy, and he had thought it his duty to consider whether he could, consistently with this duty and with other avocations which he could not abandon, become a member of this committee. Dr. Quain had kindly undertaken to satisfy all his scruples on this head; and if, as he understood, the duty of the committee was to be limited to considering the defects which exist in the present Pharmacopœia, with a view to a reprint rather than to a new edition, with certain supplements of importance, then he should with great pleasure take his part in the work.

Dr. Corrigan called attention to two things which do not exist in the present Pharmacopœia. The first is a posological table for the use of the chemist; the other is a table showing the preparations of any particular medicine. Take camphor, for instance. If he wanted to know where or what was the form under which the preparations of it are now given, after a great deal of hunting in the index, he found the preparation was under "aqua camphoræ." So again with iodine, he found in the index only the word "iodine." What he wished was all the preparations of iodine indicated so that he could at once lay his finger on what he wanted. In the same way, if he turned to "plumbum," he had to turn to two or three preparations before he found the one he wanted.

Dr. Andrew Wood also spoke in favour of inserting a posological table, and in support of what Dr. Corrigan had said with regard to the index. Another thing was, they had not sufficiently marked in the Pharmacopœia the changes that had been introduced. Were these points attended to, many of the objections to the Pharmacopœia would cease.

Dr. Christison said it might be considered as settled that the two points mentioned by Dr. Corrigan and the additional point spoken to by Dr. Wood would be attended to.

Dr. Alex. Wood said, after the condemnation passed upon the work from very high quarters, it would be reassuring to the public to hear from Dr. Christison that certain objections to the Pharmacopœia would be remedied in a future edition. At the same time, there had been an excess of criticism on the Pharmacopœia. Many practitioners seemed to have expected from the Council a Dispensatory, and the sooner any intention of that kind was disavowed the better. He thought the Pharmacopœia a most admirable book, and he was assured by the first chemists and druggists in Edinburgh that, with one or two exceptions, the formulæ for the preparations are unexceptionable.

In reply to Dr. Apjohn, the President said he understood the committee would report to the Council.

Dr. Quain said that would be quite impossible. The fact that there were three editions of the Pharmacopœia before the Profession called for an authorized revised copy; therefore, so far as this committee was concerned, he hoped there would be no inquiry about the past, as the labours of the committee had reference to the future. When the payments on account of the past Pharmacopœia came up, then would be the time to raise any discussion.

The motion was put and carried unanimously.

THE MEDICAL CIRCULAR.

WEDNESDAY, JUNE 8, 1864.

THE MEDICAL COUNCIL AND THE MEDICAL CORPORATIONS.

The General Medical Council, in October, 1863, addressed a circular to all the bodies mentioned in schedule (A) of the Medical Act, requesting them to furnish a copy of their regulations relative to education and examination, and at the same time sending a copy of the Recommendations of the Medical Council in reference to those subjects. The Council also requested, in case the regulations of any of the bodies differed from the recommendations of the Medical Council, to be favoured with such observations as might explain the discrepancy; and the Council desired generally to receive the opinions of the corporate bodies as to the whole subject of medical education and examination.

In reply to this circular, answers were received from all the corporate bodies; and these answers have been read to the Council, and are now printed in one of the published minutes of the proceedings. In perusing and analyzing these answers, it is not at all easy to give a concise and accurate description of their general scope and tendency, inasmuch as they all differ from one another, and most of them dissent from the recommendations and resolutions emanating from the General Council. Some of them declare at once that they decline to comply with the recommendations; others assert that they do comply in the spirit, if not in the letter; many express their willingness to comply if the rules are made compulsory upon all the bodies alike; some allege that they cannot comply, in consequence of local and special circumstances, or legal restrictions; others, that compliance is inexpedient and injurious to professional interests.

Ridiculous and paradoxical as it may seem, and on the principle that the little fish are caught in the net which is broken by the big ones, among the few bodies which appear to have conformed entirely to the recommendations issued by the Council in 1861 were the Apothecaries' Society of London and the Apothecaries' Hall of Ireland. That there may be no mistake whatever on this subject, we subjoin an extract from the printed Regulations of the former body, to be observed by students intending to qualify themselves to practise as apothecaries in England and Wales. This document bears date September 2, 1862; and we must observe that the great points on which the Medical Council was most stringent, and on which it met with the strongest opposition from most of the corporations, were the rules as to spending *four* full sessions of attendance at hospitals and lectures on the part of the students, and as to the necessity of passing a preliminary examination *before the commencement of medical studies*, which is defined as the time of commencing studies at a medical school. The regulations of the London Society of Apothecaries, then, in addition to the evidence of having served an apprenticeship or pupilage of not less than five years to a qualified practitioner, which period may include the time spent in attending lectures and hospital practice, required from the student evidence "of having passed a preliminary examination in arts as a test of general education. This examination must be passed *before the commencement* of *professional studies*, which is defined by the Medical Council 'to be the time of *commencing studies* at a *medical school*.' And of having pursued a course of medical study in conformity with the regulations of the Court.

"COURSE OF STUDY.—Every candidate whose attendance on lectures shall commence on or after the 1st of October, 1861, must attend the following lectures and medical practice during not less than *four* winter and *four* summer sessions; each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 15th of October; and each summer session to extend from the 1st of May to the 31st of July.

FIRST YEAR.

Winter Session.—Chemistry, Descriptive Anatomy, Physiology.——*Summer Session.*—Botany, Materia Medica and Therapeutics, Practical Chemistry.

SECOND YEAR.

Winter Session.—Anatomy and Physiology, Anatomical Demonstrations and Dissections, Principles and Practice of Medicine, Clinical Medical Practice.——*Summer Session.*—Midwifery and Diseases of Women and Children, Clinical Medical Practice.

THIRD YEAR.

Winter Session.—Principles and Practice of Medicine, Clinical Medical Practice and Morbid Anatomy.——*Summer Session.*—Clinical Lectures, Forensic Medicine and Toxicology, Clinical Medical Practice and Morbid Anatomy.

FOURTH YEAR.

Winter Session.—Practical Midwifery, Vaccination, Clinical Medical Practice and Morbid Anatomy.——*Summer Session.*—Practical Midwifery, Vaccination, Clinical Medical Practice and Morbid Anatomy."

Thus, it will be observed that the attendance for four full years on lectures and hospital practice was not only rendered compulsory on all students, but the course of study in each of the four years was sketched out for their guidance. In this respect, therefore, the curriculum was certainly more full than that of the College of Physicians, which, although requiring that four years should be spent by the student in acquiring professional knowledge, distinctly states (see the printed regulations of the Royal College of Physicians for the present year and former years, under the head of "Licentiates") that "at least *three* years shall have been passed at a recognised hospital or hospitals, the other year (the last) being passed at a medical school, hospital, *infirmary, or dispensary* recognised by the College."

It is quite true that when the Society of Apothecaries found that nearly all the corporate bodies in schedule (A) required only three years of compulsory attendance at a medical school, and that the Medical Council acquiesced in this view, they seem to have dropped one year of such attendance in their regulations of 1863. We stated that they *followed* other bodies in so doing, but we readily admit the correction we received in the letter we published last week from the Registrar of the London College of Physicians: they could not be said to follow the latter body; they rather *joined*, or *concurred* with it.

The Apothecaries' Hall of Ireland appears to have been equally humble in obeying the recommendations of the

Medical Council, for we find the Governor of that Corporation writing thus to the Council, in a letter dated Dublin, November 6, 1863 :—

"I beg herewith to transmit copies of the regulations of the Hall, and to observe that they are entirely in conformity with the recommendations of the Medical Council, and are literally carried out, with the exception of Nos. 11, 13, and 24—the former two of which refer to the registration of medical students, and the last to the requirement of a statement from candidates for examination, as to whether they have been rejected by other examining boards."

The exceptions referred to are merely formal and trivial matters which require no particular remark.

The chief recalcitrant body against the recommendations of the Medical Council, as we have often remarked, was the College of Surgeons of England; but now that this body had triumphed over the Council, its recalcitration is no longer treason, for success has stamped rebellion with the character of authority. We must also admit that the College gives reasons for the course it has pursued, and that these reasons are by no means destitute of weight. On one of the chief points insisted upon by the Medical Council, the College of Surgeons of England concurs,—namely, that four years must be devoted to professional study between the preliminary examination and that for the diploma of member—but the College firmly protests against the necessity of regarding the commencement of professional study as the entrance at a medical school, and it argues that "a pupilage for a short time to a surgeon in general practice, either holding office in a public institution or possessing other satisfactory means of affording practical knowledge," is a valuable method of "practical training, which leads at each step to real knowledge, and forms the best preparation for the lessons of the medical school." The College considers that a preliminary training at a workhouse, infirmary, or dispensary, in town or country, or a club or union practice, in which the pupil becomes acquainted with the names and treatment of various diseases, and with the appliances of medicine and surgery, is, so far from being objectionable, positively advantageous. In these remarks there is considerable force, because we think that, without such previous introduction, the professorial lectures must be wholly unintelligible. Let us imagine a youth who has just passed his examination in classics and mathematics, but entirely unacquainted with the very alphabet of Medicine and Surgery, suddenly placed in a lecture-room among a crowd of students, where he hears a teacher discoursing about matters of which the neophyte knows nothing, and in a language filled with technicalities. Surely the most conscientious student must give up in despair the attempt to follow the lectures which a little previous training might have rendered intelligible and useful. We cannot but regard the plan of discarding preliminary professional training, or of putting it at the end of the curriculum instead of at the beginning, as a system of putting the cart before the horse, to which the term preposterous may be very fairly applied, the word *præposterus*, in its etymological signification, in which it is used by the Roman authors, meaning *having the last first* (see Latin Dictionary). But then the question may be asked, Does the College of Surgeons insist, in all cases, upon ample evidence that such preliminary professional training has been really secured? We cannot forget that, in former times at least, druggists' shopboys and pastrycooks men have, in a very short period, been metamorphosed into surgeons, owing, it may be, to deception practised upon the College.

SUMMARY OF THE WEEK.

THE ELECTION OF COUNCILLORS AT THE COLLEGE OF SURGEONS.

We last week alluded briefly to the fact that Mr. Gulliver intended to offer himself as a candidate for election into the Council. We now learn that his chances of success are very considerable, and that he will be supported by a great number of the fellows. Our own opinions have been already so fully expressed as to the unfairness with which we conceive Mr. Gulliver was treated last year, in being passed over as an examiner, that we need scarcely state we shall be rejoiced if Mr. Gulliver is elected. As an original writer and thinker, he is an ornament to British scientific surgery, and the College ought to be proud of having such a man among its governing body.

THE ANNIVERSARY FESTIVAL OF THE SOCIETY FOR THE RELIEF OF THE WIDOWS AND ORPHANS OF MEDICAL MEN.

The seventy-sixth anniversary dinner of the Society for the Relief of the Widows and Orphans of Medical Men in London and its vicinity has just been held at the Albion Tavern, under the presidency of Mr. Thomas Arthur Stone, together with about eighty gentlemen. He was supported, as on former occasions, by several distinguished descendants of the original promoters of the Society—as Mr. Baillie, son of the well-known Dr. Matthew Baillie; the Hon. G. Denman, son of the late Lord Denman, and grandson of the celebrated Dr. Denman. The great feature which marks the present history of the Society, and was brought prominently into notice at the festival, is the recent grant of a Royal Charter of Incorporation, which, by removing certain pre-existing disabilities, enables the directors to lay out their money to greater advantage than was formerly the case, and thus to increase their income, and consequently to extend the benefits conferred upon the recipients of the funds. The balance-sheet exhibits a very flourishing state of accounts, and, indeed, the prosperity of the institution may be one reason why it is not more numerously supported. But we earnestly call upon the Profession to avail themselves of the advantages it offers, and, by the payment of a very small annual sum, to secure for their descendants the means of support in case they are left otherwise unprovided for. The Society is not a charity, but a provident institution; and the income attainable by a widow and her children must be regarded in the light of a life assurance, without being nearly so expensive. For two guineas a year a sum may be obtained equal to the interest of several thousand pounds. The office of the Society is at 53 Berners street, Oxford street, and the secretary is Dr. Merriman.

ACCIDENTS AT THE VOLUNTEER REVIEW.

"The Volunteer Review in Hyde park passed off extremely well, and with remarkably few accidents, mainly owing no doubt to the excellent arrangements of the military authorities, and to the caution observed by the men in handling their weapons, and which some occasionally serious mishaps have taught them. Amongst the whole body of volunteers on the field, we hear of only one casualty, and that not severe. But, nevertheless, the statement made by the Home Secretary in the House of Commons, that the police believed that only one accident had occurred, was founded on a report from that body which must have been remarkably inaccurate. We have received the following list of casualties amongst the spectators from a reliable source :—

"Alfred Harwood; fractured clavicle, fractured humerus, &c. George Matthew; fractured base of skull. Henry Masters; concussion of the brain. Joseph Moon; scalp wound. Henry Turner; grazed wrist. Timothy Oldbury; cut face, &c. Dennis Mahony, bandsman, 2nd Surrey; contusion of the eye. David Armiger; wounded hand, &c. Edward Gerrard; fractured patella."

We have copied the above from the 'Lancet,' and we must observe that, considering one poor man had a fractured clavicle, fractured humerus, &c. (how many more fractures does the *et cetera* include ?), another a fracture of the base of his skull, another a concussion of his brain, another a fractured patella, another a scalp wound—to say nothing of the minor occurrences—we do not see how the number of accidents could be called "remarkably small," seeing that the occasion was a mere holiday gathering, and that there was no firing even in sport. But, on reading the whole article, we are not quite clear whether the writer means that the accidents, few as they were, were mainly owing to the excellent arrangements of the military authorities, or, if he does not, whether there is any substantive in the previous sentence to which the word *owing* refers. We have heard of some multitudinous weddings among the lower orders in Whitechapel on Easter Mondays, when the right brides and bridegrooms are unable to find one another owing to the crowd and the confusion, and the wrong parties are sometimes married by mistake; and such appears to be the case with most of the relatives and the antecedents in the above few sentences, the great difficulty being to find out the couples which match one another. But as we think we have mastered the problem, though after some trouble, we merely present the quotation as a puzzle for such of our readers as may be fond of working out literary equations, and eliminating the x, y, z, from a somewhat complicated philological riddle.

THE RIGHT OF PAROCHIAL AUTHORITIES TO CONTROL THE CORONER'S OFFICERS.

COUNSELS' OPINION.—For a considerable period past there has been a dispute between the Vestry of St. Pancras and Dr. Lankester, as coroner for Central Middlesex, as to the right of the latter to send his warrants to any sworn constable he pleases, and at one time it bid fair to involve the parties in litigation. This question has, it is believed, now been brought to a conclusion by the opinion of Mr. Lush, Q.C., and Mr. Welsby.

The "case" recited the various facts, and Counsel were requested to advise the vestry—1. Whether they have any, and what, power to compel the coroner to deliver his precepts to Edwin Holland, the beadle appointed by the vestry ? 2. Whether Murray can legally execute such precepts, summon the juries, and receive the payments made by the Justices of the Peace ? 3. Whether the vestry have any, and what, remedy against the coroner ? 4. Whether the vestry have the right of control over the constable in the execution of his office as claimed ? 5. And generally on the relation between the coroner and the vestry in this matter, and what, if any, proceedings at law should be taken by them ? OPINION.—1. We are of opinion that the vestry have no such power. The warrant of the coroner is directed to all constables and peace officers within the parish or other district in which the death occurs, in respect of which the inquest is to be held, and may be executed by any constable or peace officer to whom he thinks fit to address and deliver it for that purpose. And we do not find that the vestry have any authority under their act to appoint constables or peace officers, or to designate under the denomination of "coroner's beadles" or otherwise, any particular constables or peace officers to perform the duty of executing the warrants of the coroner. 2. We think he may. He is a constable for the metropolitan district, which seems to us to be all that is necessary for this purpose; nor do we think that his right to receive such payments is affected by the alleged irregularity in not taking the order of his inspector in the matter. 3 and 4. It follows that we answer both these questions in the negative, and that 5. We do not advise any proceedings by the vestry against the coroner or Murray.

May 25, 1864. (Signed) ROBT. LUSH. M. N. WELSBY.

A motion that this opinion of counsel be referred back to the committee, to report to the board what steps should be taken in the matter under the circumstances, was negatived by a majority of 25 to 12, and the case and opinion were then ordered to be recorded on the minutes.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 24.

JOHN HILTON, F.R.S., Vice-President, in the Chair.

A paper, by Mr. BERKELEY HILL, was read on

THE OCCURRENCE OF A STERNO-CLAVICULAR MUSCLE.

I have lately found a muscle on each side of the body which passed between the front of the first piece of the sternum and the fore part of the clavicle. The subclavii, in this instance, were quite distinct from this rare muscle, and had their usual disposition. The muscles were well-marked rounded slips, tendinous at their attachment to the sternum, and fleshy at their clavicular attachment. The occasional occurrence of such a muscle is mentioned, as far as I know, by Haller only, in his 'Elements of Physiology.' All the other authors who advert to peculiarities of the subclavius muscle merely describe its attachment to the coracoid and acromial processes of the scapula. Among the commoner animals which have a clavicle, Meckel says that the bat has a well-formed subclavius, and I find by dissection that the mole's subclavius arises altogether from the sternum. But these instances are hardly sufficient to establish any homology between the sterno-clavicular muscle and the subclavius in lower animals.

Mr. CHARLES H. MOORE communicated an account, by Dr. Murray, of a

CASE OF ANEURISM OF THE ABDOMINAL AORTA, WHICH WAS CURED BY COMPRESSION OF THE ARTERY IMMEDIATELY ABOVE THE TUMOUR.

The patient is a spare man, aged 26 years. His occupation as a pavior has required him to use a large wooden rammer for driving paving stones into the ground. Often in making strenuous exertions he has overreached himself, and subjected the trunk of his body to severe straining. Eleven months ago after hard work he was seized with severe pain in the back. Two months later the same pain began to be felt in the abdomen, catching his breath, and very severe. About two months ago he began to feel

a beating in his belly, and shortly afterwards became a patient at the Newcastle-on-Tyne Dispensary under Dr. William Murray, who, after a few examinations, became convinced that he had an aneurism of the abdominal aorta. This opinion was shared by the Medical Officer of the Dispensary. The following was the condition of the patient previous to the treatment:—His abdomen was somewhat spare, so that a distinct pulsation can be seen opposite the umbilicus. On applying the hand a hard, and slightly movable tumour, of a distinctly globular form, is to be felt. It pulsates very strongly, and the pulsations impinge upon the hand with a sudden stroke, and the expansion of the tumour very distinctly separates the hands when applied to it. The tumour is of about the size of a large orange; when "the pressure" is made on the aorta above it, all pulsation ceases, and when it is removed a distinct thrill is felt to accompany a rush of blood into the tumour. A slight bruit is heard over the tumour. (A line drawn across the abdomen over the umbilicus touches at either end the margin of the last rib, and encloses between the free borders of the ribs a triangular space—the epigastric region. Over the left half of this space there is just room enough above the tumour to compress the aorta against the spine.) The aorta below the tumour can be felt, and its pulsations seem in no way to depart from their normal characters. Bowels slightly constipated. Pulse good and normal. General health good; but he is worn out with pain and consequent loss of sleep. No evidence of degeneration of arterial system. All palliative treatment having failed to relieve him, I proposed to apply a tourniquet (an ordinary horseshoe tourniquet) above the aneurism, and thus attempt to cure by compression. It happened, as I have before shown, that the aorta could be compressed above the tumour; and this was most completely accomplished by the tourniquet, one blade of which was applied over the spine and the other over the spot above indicated. Having taken my patient to the Northumberland and Durham Medical Society, I obtained there, from the President (Dr. Heath) and others, ample confirmation of my diagnosis; at the same time I proposed my plan of treatment. On Saturday, April 16, the patient was put under the influence of chloroform, pressure, by means of the tourniquet, was kept up for two hours. On removing the pressure, no apparent effect had been produced. The pressure completely commanded pulsation in the tumour, except during occasional momentary displacement of the instrument. After an urgent entreaty on my part, the patient again submitted to the treatment on Tuesday, April 19. After careful re-examination by Dr. Heath and myself, it was concluded once more that there could be no reasonable doubt of the nature of the disease. The pressure was again used and maintained, with but momentary intermissions when the instrument became displaced, but even these were avoided during the last hour, as I carefully held the instrument in its place, and had the patient very fully under the influence of chloroform. After about five hours the pressure was removed, and its removal showed that now very little pulsation existed in the tumour. Beyond a little shivering and numbness, with coldness of the feet and legs, nothing of an untoward nature followed. In the evening, after a most careful examination, I failed to detect the slightest pulsation in the tumour or in the aorta below it. On Wednesday, April 20, the patient was restless and sore; legs feel numb, and a sensation of pins and needles in the feet. In consultation with Dr. Heath, the following observations were made and confirmed by that gentleman:—"There is no pulsation in the tumour, which is now perfectly stationary, hard, resistant, and lessened in size; nor are any pulsations to be felt in the aorta below the tumour, in the iliacs, or femoral arteries." Thursday, April 21.—The patient is much better. Says "he is more free from pain than he has been for several months." No pulsation in tumour or femoral. Pulses can be felt at one or two points in the abdominal wall. Friday, 22nd.—With Mr. Lightfoot, who carefully examined the case, the following points were made out, and verified by that gentleman:—"A solid hard tumour, of about the size of an apple, lying to the left of the umbilicus, can be felt, and during deep expiration can be seen. It is motionless to the eye, and, by the hand, the slightest possible forward movement can be distinguished at its upper border, as if communicated from the aorta pulsating above." No expansile movement, thrill, or bruit can be made out. All numbness is gone from the legs, and the patient declares he is quite well. Monday, 25th.—Still improving; is moving about freely. No pain since treatment. The tumour is now much diminished in size, and no pulsation can be distinguished in it. The patient has been out this morning, and walked about a quarter of a mile. His legs failed him once or twice during his walk, owing, he says, to a sensation of numbness in them. When his exercise terminated he felt a numbness from the umbilicus downwards for several minutes. Several medical gentlemen examined him at this period, and their unanimous conclusion was, that all pulsation had ceased in the aorta and the large arteries below the tumour. Among these were Dr. Gibb, Messrs. Fips and Armstrong, Mr. Rayne, &c. May 1.—Patient still improving, and walking in the open air daily. No pain or pulsation. May 5.—Patient still improving; has been out for three hours and walked a considerable distance without other discomfort than slight weakness and numbness in legs. The most careful examination in the presence of several medical gentlemen fails to detect any movement in tumour, which is now hard and further diminished in size. May 9.—Everything in a most satisfactory state. *Remarks.*—We note in the first place that here we have a complete triumph for the advocates of compression in the treatment of aneurism, for a hitherto fatal disease has yielded to treatment lasting but a few hours, and requiring the use of a very simple expedient. Secondly, here is proof that the aorta can be blocked without violent symptoms or great inconvenience ensuing; and lastly it adds another instance of the value of chloroform, without which the tremendous pressure here used could never have been borne, even though it were to save the patient's life.

Mr. C. H. MOORE said that he heard the first half of the paper with incredulity, but in the latter half the author satisfactorily showed that the aneurism was obliterated. The chief proof was the obliteration of the vessels below the aneurism, as the cure of no tumour, except aneurism, would produce this symptom. It was strange that after such sudden occlusion of the iliac arteries there should have been no gangrene of the toes, and no anæsthesia. The diminution of the tumour to one-third its size was another proof that the tumour had been an aneurism. He (Mr. Moore) thought the slips of the tourniquet had very likely been favourable, and that the cure was by coagulation of the centre mass of blood in the aneurism.

Dr. SYMES THOMPSON inquired whether any estimate could be formed of the force required to restrain the pulsation of the abdominal aorta in this case? It would, he thought, have been satisfactory had this point been ascertained by the use of the tourniquet brought before the Society last year, by means of which the exact pressure in lbs. exercised upon a part was indicated on a graduated scale attached to the instrument. The danger to be apprehended from severe pressure upon the solar plexus must be great, and, when the patient is unconscious from the influence of chloroform, it would seem really important to have some indication of the force employed. A knowledge of the pressure necessary in one instance might also act as a check against unrestricted compression in future cases.

The AUTHOR said that the force required to arrest the flow of blood would depend very much on the state of the abdominal parietes, and on the condition of the viscera. In this case it was possible to arrest it by pressure by the thumb. The amount of pressure had not, however, been accurately estimated.

Mr. HILTON asked if the author had arrived at any conclusion as to the precise seat of the aneurism—as, for instance, if it were near the cœliac axis, or the origin of the renal arteries.

The AUTHOR said that an artery was to be felt beating near the tumour, which he fancied was the superior mesen-

eric artery. After the first attempt at compression there had been suppression of urine for thirty hours.

Dr. STEWART thought that one of the most remarkable features in this case was the absence of gangrene. He related cases in which gangrene ensued shortly after occlusion of arteries.

A paper, by Dr. W. H. DICKINSON, was read

ON THE TREATMENT OF ALBUMINURIA IN CHILDREN.

The granular kidney appears to be unknown in childhood. The only form of disease which produces albuminuria at this period of life is that which produces enlargement of the kidney and gives it a smooth mottled exterior. This is, in fact, a renal catarrh. The tubes become obstructed by an excess of their own epithelial growth, and hence arise all the evils of the disease. If only there is a free escape for the contents of the tubes, the vascularity of the gland will be relieved by secretion, and the disorder will soon be at an end. The principle of treatment must be to send as much water as possible through the organ. This fluid is devoid of irritating properties, and probably passes through the gland rather by filtration than true secretion. With these views the patients were restricted to a fluid diet. They took from two to four pints of distilled water daily, and small doses of the infusion of digitalis. When the active symptoms had subsided iron was given. Twenty-six cases were adduced in which this treatment had been pursued. Twenty-two recovered completely; three were lost sight of while improving, but while still having a small quantity of albumen in the urine; one case did badly, and eventually died under other treatment. Many of the cases were of great severity. These results appear better than those afforded by other methods. Among the in-patients at the Children's Hospital otherwise treated, eleven died out of thirty-nine; and of sixty-nine cases treated by Dr. Miller in dispensary practice, eight died. It was found that on an average the little patients were restored to apparent health in thirty days, while fifteen days more were needed to get rid of the last traces of albumen. The use of the water did not seem in any case to increase the dropsy, but the contrary. It was usual, however, when the swelling was great, to let the digitalis set up a certain amount of diuresis before ordering the full quantity. The subsequent use of iron was believed to correct the effects of the disease, without influencing the disease itself. On the occurrence of secondary disorders, such as convulsions, or acute inflammatory attacks, it was argued that the treatment of the renal mischief should be sedulously persisted in, with such additions as might be called for. The anæmic state of brain in uræmic convulsions, and their frequent occurrence after the exhaustion of diarrhœa or vomiting, were urged as reasons for abstaining from depressing remedies. A case was cited in which, under these circumstances, small doses of opium had been used successfully. A case was also given in which acute pleurisy had passed off under the use of only local measures. The paper professed to deal only with the albuminuria of childhood.

Dr. FULLER had had opportunities of witnessing the author's treatment, but chiefly in adults, in whom it was not so successful as in children. In adults the renal affection was of longer standing. He had tried it in a child in private with success. It was successful in the dropsy of adults, but not so uniformly so as in dropsy in children after scarlet fever. If Dr. Dickinson's views were correct, it was easy to understand that it should be more useful in children than in adults.

Dr. BASHAM said there were many points of practical value in the paper, and yet one or two things for comment. First, in cases where the renal affection followed scarlet fever, let the treatment be what it might, the majority of patients did well. No doubt the diuretic influence of water was beneficial, but he thought the theory brought forward was open to a difference of opinion. He ventured to think that there was not merely a blocking up of the tube, but also some change of the gland-cells—they had become effete cells, and accordingly were thrown off, and these, of course, obstructed the tube. But we know that Nature tries to get rid of them, and no doubt diluents are of help in this way. He should, however, think the natural tendency of such cases to do well had more to do with recovery than the treatment.

Dr. HILLIER had tried Dr. Dickinson's plan, and had found it scarcely so satisfactory. He (Dr. Hillier) agreed with Dr. Basham, that such patients, however treated, if seen early, would nearly always do well. His plan of treatment was to keep them in bed, to use hot-air baths, to give purgatives and good diet. Occasionally he had under care a severe case, and then had tried the water plan, but had been obliged to resort to other means. Perhaps, however, he had been too timid. In one case purpuric symptoms came on. There was considerable hæmaturia and epistaxis. With the water treatment the patient did worse, but when it was given up and gallic acid was administered, the patient recovered.

The AUTHOR, in reply, said that he was quite aware that the majority would get well if left alone, but a great number would not. He had been able to collect a large number of cases of deaths in the post-mortem books of St. George's Hospital. In reference to Dr. Basham's remarks, he said that the first changes were, he believed, in the quantity and not in the quality of the epithelium. In reference to Dr. Hillier's want of success, he would fall back on the explanation which Dr. Hillier himself had suggested, viz., that the treatment was not persevered in. The only fatal case in the paper was the one in which the vapour bath had been used.

MR. BAINBRIDGE asked if the treatment would have been equally successful without the digitalis? He had seen many such cases during the last month, and the patients generally were thirsty, and, as a consequence, without any special direction, drank a great deal of water.

The AUTHOR said that the water treatment had been tried alone in three cases.

DR. STEWART related a case of dropsy following scarlet fever occurring in a woman who had recently been confined. Suddenly convulsions came on, followed by unconsciousness. Cupping the loins, and other measures, were followed by success, and he thought it a case in which the use of diluents would not have led to an equally favourable result.

Dr. BASHAM said that he thought that if any pathologist well versed in the use of the microscope would examine the gland cells of the kidney of a child who had died by accident, and then those of one who had died from renal disorder, he would find a well-marked difference. In the latter the cell was cloudy, and the nucleus obscure. It had become an effete and imperfect cell.

Dr. FENWICK said that he had examined the mucous membrane of the stomach in scarlet fever patients, and had found changes in the epithelium there as well as in that of the kidney.

In reply, Dr. DICKINSON said that no doubt there was a change in the cells, but not primarily.

A paper, by Dr. EDWARD HEADLAM GREENHOW, was read on a

CASE OF CONGENITAL IMPERFECTION OF THE MAMMÆ, SEXUAL ORGANS, AND HEART.

The subject of this very rare and remarkable case was an unmarried female servant, aged twenty-two. She had been all her life subject to difficulty of breathing when in exercise, and liable to cough from exposure to cold, but had become worse in these respects since she had been employed as maid-of-all-work. Had never menstruated, nor had any vicarious hæmorrhage. Appearance, hair, and voice feminine. Pulse variable, and very small and irregular in the erect position, more frequent, of better volume, and quite regular when the patient lay down. There was a remarkable depression in the sternum, and an exquisitely tender spot about the middle of the ensiform cartilage. No trace of mammary glands could be discovered, but there were rudimentary nipples. No evidence of pulmonary disease, præcordial dulness much extended, and there was a triple heart sound—the third sound, intermediate between the systole and distole, being sometime supplanted by a murmur. Pelvis abnormally small, and genital organs,

as far as examination could be made, imperfectly developed examination either per vaginam or rectum. Dr. Greenhow no os uteri being discoverable, nor any ovaries felt on had found only four cases on record in any respects similar to the one he described, all of which he quoted, showing that they also differed materially from it in various characteristic symptoms. He regarded the case as a very interesting one of congenital imperfection, the result of arrested development.

THE HARVEIAN SOCIETY.

SATURDAY, APRIL 21.

Dr. GRAILLY HEWITT in the chair.

Dr. COCK mentioned a case of

SPONTANEOUS GANGRENE OCCURRING IN A CHILD.

The whole of the left leg was in a state of dry gangrene, and 2″ below Poupart's ligament there was a line of demarcation, so that the back part of the thigh remained healthy. The illness lasted three weeks. On post-mortem examination, the arteries were found to be quite open. The iliac vein was filled up for about 10″. The coagulum was fully organised, and the clot adhered firmly to the interior of the vein.

Dr. G. HEWITT remarked that this was indeed a very rare history of gangrene. Plugging of the veins was not uncommon in debilitated subjects, but in Dr. Cock's case there appeared no sufficient reason for the occurrence of gangrene.

Dr. ROYSTON communicated a case of senile gangrene occurring in a man aged sixty. The toes had ulcerated and come away.

A paper was read by Dr. COCK on

LARYNGISMUS STRIDULUS.

Dr. Cock referred to the papers on rickets by Dr. Jenner, which appeared in the 'Medical Times and Gazette' of 1860. Laryngismus stridulus is accompanied by, or caused by, a narrowing or closure of the glottis. In the healthy larynx the vocal cords are widely separated in common respiration. The superior laryngeal nerve supplies the crico-thyroid muscle and the thyroid body; the recurrent laryngeal is the motor nerve of the larynx. Dr. Reid had shown that, if the inferior laryngeal nerve be divided, or the pneumo-gastric trunk above the origin of the nerves, there is no constriction of the glottis, but a paralysed state of its muscles. After the first paroxysms occasioned by the operation, a period of quiescence and freedom from dyspnœa occurs, the respirations being performed with ease, as long as the animal remains quiet. If it struggles, the arytenoid cartilages, carried inwards by the current of air, fall on the opening of the glottis and suffocate the animal; so that, to prolong life, tracheotomy is required. There can be no doubt, then, that the superior and inferior laryngeal nerves constitute the circle of incident and motor nerves by which the aperture of the glottis is governed. Laryngismus stridulus comes on suddenly, as when food "goes the wrong way.' Should the child recover from the attack, the respiration remains shallow in character, and anything which causes a deep inspiration may bring on an attack. Also, Dr. Cock has usually found some catarrh accompanying the affection. A peculiar form of the affection sometimes is found in rickety children. The child wakes and immediately commences to breathe in a crowing manner. Having seen, as physician to Farringdon Dispensary for some years, a large number of these cases, he had come to the conclusion that it was nothing more than a symptom. In rickety children we have all the conditions for its production—(1), slow development of the teeth; (2), softening of the bones, and among others the hyoid; (3), great weakness of the muscles. These circumstances, with the addition of enlarged cervical glands, cause pressure on the pneumo-gastric nerve. The muscles of the rickety child are unable to overcome the action of the diaphragm in efforts to cough, and the child becomes insensible for a short time, during which time the glottis closes, soon to reopen with a hoop. The arytenoid cartilages fall in and the muscles of expiration are semi-paralysed. The irritation, again, may commence from the branches of the fifth pair in painful dentition; or, again, improper food may irritate the branches of the pneumo-gastric nerve. The nerves of the skin, again, may be the excito-motory ones; and, lastly, the irritation may be cerebral instead of peripheral.

Dr. DRYSDALE observed that the Society had to thank Dr. Cock for his most instructive papers, first upon the rickets and now upon one of its frequent symptoms. No disease was more important than rickets, since it was one of the commonest causes of death among children, especially of those who were born in crowded alleys and were ill fed and ill cared for. They were carried off in thousands by bronchitis and fevers, which their feeble organisations were unable to withstand. Rickets, scrofula, and fevers, indeed, unfortunately still remained what have been styled by Malthus, Chalmers, and others, the "positive checks to population," even in this country. As to laryngismus, he had not usually considered it as often fatal, nor could he agree with the author in having found it so constantly accompanied with catarrh.

Dr. GRAILLY HEWITT considered the physiological account given by Dr. Cock of the causation of laryngismus as quite correct. He had never seen two cases of the affection precisely similar. In some cases pressure within the chest had appeared to cause it. He was surprised to hear Dr. Cock speak of death as being caused by laryngismus. As to treatment, he believed that fresh air and nutritious diet was all that was indicated in such cases. Even among the better classes the children who are subject to rickets are ill nourished, and this symptom resembles those of other parts of the body. The child is usually puny, with small face and undeveloped lower jaw, and does not "get on."

Dr. TILBURY FOX observed that diet had been mentioned in rickets, and he had recently examined many of the different foods given to children, such as maizena, &c., and had found them all to consist entirely of starch. This was one of the causes of bad nutrition among children. Messrs. Bullen and Reynolds had introduced a food which contained the branny covering of the grain and the phosphate, which he (Dr. Fox) considered a great improvement. He had found that mothers who are suckling their children, and at the same time are menstruating, are apt to render those children rickety.

Dr. DRYSDALE presumed that Dr. Fox did not propose giving any of these "foods" to children under eight months. He had found that the most fruitful source of rickets was feeding infants on baked flour, biscuits, &c., before their stomachs would digest them. Infants should live on *milk* for seven or eight months.

Dr. POLLOCK, in reply to a question, observed that, in his experience, tubercles and rickets very rarely occur together in the same child. He had long thought that the best food for children was flour twice cooked—*Hard's food*, for example. With respect to menstruation being a cause of rickets, the physicians in Italy were in the habit of saying that this seemed rather to refresh the milk. It was in Italy the custom for a large number of the women to suckle their children for two or three years, in order to prevent the addition of another child to an already too numerous family.

Dr. COCK replied that Dr. Fox had brought forward menstruation during lactation as a frequent cause of rickets, and doubtless any cause which rendered the mother weakly, whilst either pregnant or suckling, would tend to the production of rickets. Persons in good circumstances have rickets, although the disease is most frequently observed amongst the children of the poor. He believed that the rickety diathesis came more generally from the mother than the father. As to treatment: When the mother is weak, we ought to use cow's milk, with beef tea and wine, to nourish the child. Lime-water is valuable as an astringent, and carbonate of soda as an antacid. With regard to the simultaneous occurrence of tubercle and rickets, there could be no doubt that, after the age of twelve, they were often found conjoined; and even in infants at the

breast, in some cases, rickets had been found conjoined with tubercle in the lungs. Children will recover from laryngismus and rickets frequently, if they can be sent all day long into the open air.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

MAY 30TH.

VACCINATION.

Lord Lyttelton wished to ask the President of the Council a question of which he had given him private notice, respecting the intentions of the Government in order to secure the more effectual enforcement of vaccination. The returns of the Registrar-General showed a large amount of preventable disease and of deaths from small-pox, and it was very desirable that something should be done.

The Earl of Shaftesbury said the subject was one which eminently deserved the consideration of the Government. His lordship, in confirmation of this opinion, quoted the following extracts from the report of the Epidemiological Society :—

"3,240 persons die, on an average, every year in England from small-pox. In the metropolis alone the average annual mortality from this disease exceeds 700. At epidemic periods the mortality assumes much higher proportions, and in the epidemic which ravaged London last year and has not yet quite ended, nearly 2,500 lives have already been sacrificed. . . Nothing can be more certain than that, if all were thoroughly well vaccinated in early infancy, small-pox might nearly be banished from our death registers. But it should be emphatically stated that this cannot be accomplished by the mere extension of vaccination, unless means be taken at the same time to secure the more complete and effectual performance of the operation. . . It appears to the committee very inexpedient that the control of public vaccination should be vested in two distinct Government boards, and they are of opinion that the powers now exercised by the Poor-law Board should be transferred to the Privy Council."

Earl Granville replied to the question of the noble lord, but his answer was perfectly inaudible.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 26th ult. :—Alexander Clement Rayner, Bedford; George Huntsman Shaw, St. Bartholomew's Hospital; Spencer Henry Simpson, Stowmarket, Suffolk; William Griffith Williams, Haverfordwest.

The following gentleman also on the same day passed his first examination: William Lively Shepard, St. Bartholomew's Hospital.

CONVERSAZIONE AT APOTHECARIES' HALL.—On Tuesday, May 31, the Master and Wardens of the Society of Apothecaries gave a brilliant microscopical *conversazione* at their Hall in Blackfriars. All the great manufacturers of microscopes contributed instruments. It would be impossible to give anything like a full list of the varied and beautiful objects displayed, but we may notice a few of them. Among those exhibited by Messrs. Powell and Lealand was the circulation of the sap in the Vallisneria, shown by a $\frac{1}{25}$-inch object glass. Mr. Ross exhibited some objects under Kelner's large field eyepieces. Dr. Miller exhibited a living specimen of the Conochilus Volvox, a peculiar form of wheel-animalcule, and a small living Medusa. In another part of the room was a living specimen of the Volvox Globator, an organic being placed on the confines of the animal and vegetable worlds, but now considered as a plant, though possessed of the power of rapid movement. A number of binocular microscopes were shown by Messrs. Crouch, Murray and Heath, Edmund Wheeler, Gould, Smith and Beck, and others. But, besides microscopes and microscopical specimens, there were many other objects exhibited of great scientific interest. The walls of the ancient hall and of the library were covered by large coloured drawings illustrative of the classes and orders of the animal and vegetable kingdoms, the principal groups of them showing magnified representations of microscopical structures and dissections, and arranged as far as possible in the order of progressive development of organic forms. Among the most conspicuous of these were the series of drawings illustrating Comparative Anatomy, contributed by Professor Grant; of the structure of the Foraminifera, by Dr. Carpenter; of the anatomy of plants, by Professor Bentley; and of the forms of the Acalephæ, or sea-nettles, by Mr. Mummery. Mr. Ward, F.R.S., the distinguished botanist, also exhibited a great variety of specimens of dried plants, besides contributing a great number of living ones, and a multitude of botanical plates and drawings. Dr. King and Dr. Stephen Ward showed a series of very interesting ethnological water-colour sketches taken from life by Mr. Say, Mrs. Stephen Ward, Miss F. Corbaux, and others. Mr. Carruthers exhibited some of the first original sun-pictures on metal plates; with etchings from the same, executed by M. Niepce in 1827. The Messrs. Wheeler showed various experiments illustrating the allotropic conditions of several elements. They also electrolysed water, making use of carbon poles; and showed that when these were employed, carbonic acid was obtained at the negative pole in place of oxygen. Another experiment illustrated the bleaching effects of nascent hydrogen, the gas, at the moment of disengagement, decolorising a solution of indigo, but having no effect on the same solution when passed into a wash bottle containing it. On Wednesday morning, when the microscopical exhibition was visited by a large number of ladies, the same gentlemen made a series of brilliant experiments with twenty-four cells of a carbon battery of their own construction. With this battery they produced a powerful electric light, and showed the arc of the thallium flame on the screen. In these experiments they were assisted by Mr. William Crookes, the discoverer of the metal Thallium. Iron and zinc were burnt with ease by means of the battery. They also exhibited the magnesium light, and showed some striking experiments illustrating the fluorescent property of a solution of sulphate of quinine. In the same room, Mr. Ladd exhibited his exceedingly interesting experiments of passing electricity through a vacuum, illustrating the phenomenon of the Aurora Borealis; and through different gases, as hydrogen, nitrogen, and carbonic acid, showing the different colours and bands produced by the passage of the electric fluid through these media. The *conversazione* was quite successful and was very numerously attended, particularly so on the Wednesday morning, when the rooms were thronged with ladies, who took a lively and most intelligent interest in the proceedings. We have been informed that many of the arrangements, especially in the way of decoration and ornament, were made with the previous co-operation of many of the fair sex, whose taste was in many places conspicuous, although their handiwork was unseen and their names unannounced.

CAIUS COLLEGE, CAMBRIDGE.—Charles Henry Ralfe, M.R.C.S., of King's College Hospital, has obtained the Caius College scholarship in Anatomy.

MEDICAL CONGRESS AT LYONS.—Active measures are being taken at Lyons for the organization of a medical congress in September. It is to take place in the second half of the month. The admission will be free, and the transactions will consist of written or verbal communications in answer to questions framed beforehand. No paper will be put on the order of the day until the author shall have sent the heads of the same to the executive committee twenty-four hours at least before the reading. A discussion will then be invited on each question, after the conclusion of the paper bearing on such question. These measures are merely preliminary, and the final arrangements were fixed after a general meeting of the medical gentlemen of Lyons, which took place on the 19th ultimo.

NATURAL SCIENCES TRIPOS.—At a congregation of the

Senate held on the 19th ult., Dr. P. W. Latham, of Downing College, and Mr. Churchill Babington, of St. John's College, were re-appointed Examiners; and Mr. S. G. Phear, of Emmanuel College, and Mr. W. H. Brown, of Caius College, were appointed Examiners for the Natural Sciences Tripos during the ensuing year.

ST. BARTHOLOMEW'S HOSPITAL.—The following scholarships and prizes have been awarded for the winter session, 1863-64:—Scholarship in Medicine, Surgery, and Midwifery: J. W. Snook, W. V. Lush.—Scholarship in Anatomy, Physiology, and Botany: F. Bateman, T. Cole, R. Robinson. Wix Prize—T. Cole. Bentley Prize—W. V. Lush. Practical Anatomy: Foster Prize—R. P. Simpson, R. G. Rogers, T. Cole, T. Cuddeford, F. Bateman, W. Iliffe, A. C. Farrington, E. Renshaw, G. F. Webb, R. D. Broughton, J. Goodall. Treasurer's Prize—W. Square, R. B. Moore, J. Quick, F. H. Lovell, F. Ewbank, E. J. Leverton, W. H. Ellis, W. Sedgwick.

APPOINTMENT.—At a meeting of the Board of Guardians of the Stow Union, held on the 2nd inst., Mr. Benjamin F. Matthews, of Norton, was unanimously elected Medical Officer and Public Vaccinator to the No. 3 District of the Stow Union, vice H. R. Cooper, deceased.

UNIVERSITY OF CAMBRIDGE.—Dr. Humphry gives notice that his course of lectures on the Principles and Practice of Surgery will commence on Friday, July 1st, and be continued daily.

ROYAL MEDICAL BENEVOLENT COLLEGE.—The annual general meeting of the governors of this College was held on May 18th at the offices of the College; Sir Charles Locock in the chair. The report stated that during the past year no events of very marked importance to the institution had occurred, but it continued steadily the good work for which it was founded. The Council had decided upon opening the school to the sons of gentlemen not belonging to the medical profession, and with this view recommended that the second bye-law which precluded the admission as resident scholars of any but sons of medical men be rescinded, and the following adopted in its place:—"The school is intended for the education of 200 boys between the ages of eight and nineteen, none being above fifteen years old on admission. One hundred and eighty boys, at least, shall reside in the college, forty or more of whom shall be foundation scholars, the remainder being exhibitioners, and such boys, not being the sons of medical men, as shall be permitted by the Council to receive their education at the college. The foundation scholars shall be entirely educated, boarded, clothed, and maintained by the college. The exhibitioners shall pay a sum of 40*l.* a year each for education, board, lodging, and washing, without any extra charge for the use of books, instruments, &c. The scholars not the sons of medical men shall pay 63*l.* a year each for the like advantages. All payments shall be made in advance at the commencement of each term." The receipts for 1863 were greater than those of 1862 by 364*l.* The report was adopted. Messrs. H. Blenkarne, T. B. Curling, William Gilpin, C. J. F. Lord, Richard Quain, Dr. Ray, Dr. Sibson, and Messrs. A. Sterry, W. Street, and J. Ward, were re-elected members of the Council. The formal resolution altering the constitution of the school having been moved, Mr. Cattlin moved as an amendment, "That the school was intended for the education of 200 or more boys, between the ages of eight and nineteen, none being more than fifteen; 180 boys at least should reside in the college, forty or more of whom should be foundation scholars, and the remainder exhibitioners and commoners—the sons of medical men, and such boys not sons of medical men as shall be permitted by the Council to receive education at the College. The exhibitioners and commoners shall be admitted in such manner and in such relative numbers as the Council shall from time to time determine, to be supported, clothed, and fed by the College; that the exhibitioners pay 30*l.* for board, lodging, and washing, without extra charge for the use of instruments, &c., and that they should be the sons of medical men; the commoners to pay 40*l.*, and the sons of other gentlemen to pay 63*l.*" Ultimately both the original resolution and amendment were withdrawn, and the whole subject was again referred back to the Council for reconsideration, and to embody the views of Mr. Cattlin in their resolution, to be submitted to a general meeting to be called as early as possible.

THE ORIGIN OF VACCINE.—A long debate which has just taken place at the French Academy of Medicine on the origin of vaccine, on the identity of vaccine and variola, and of small-pox in the human subject with certain eruptions in animals, has at last been closed, and all the opinions brought forward have received some sort of satisfaction, at least as regards the practical inferences derivable from the discussion. Both the friends and adversaries of the doctrine of identity of the two morbid poisons entirely agree that the inoculation of small-pox must not be substituted for that of vaccine-lymph. "Variola," said Mr. Depaul, at the close of the debate, "is the concentrated virus, and vaccine-lymph the weak, diluted virus; and it would be absurd to prefer the former for inoculation." This declaration will reassure those who feared that Mr. Depaul's opinions might prove injurious to Jenner's discovery. The rest is, doubtless, an interesting question of natural history, but which can emerge from the metaphysical clouds with which it is surrounded only after long and careful experimental inquiry. When Mr. Depaul shall have brought forward positive proof of the inoculation of the small-pox of man to the cow, Messrs. Bousquet and Bouley will probably desist from their attacks on his theory. Meanwhile, thanks are due to Mr. Depaul for having finally thrown light on the origin of vaccine. As Jenner had surmised, it is now a clearly-established fact, that although cow-pox may be spontaneously developed in the bovine species, so as to constitute vaccine, it may also originate in an eruptive affection of the horse, and produce what Mr. Bouley denominates *équine*, or horse-pox. This disease, for a long time mistaken for swelled legs, quitter, and other injuries of the hoof, and more recently, by Mr. Bouley himself, for a phlyctenoid eruption of the skin, is undoubtedly a general, pustular, contagious, and inoculable disorder, transmissible from the horse to the cow, and from the latter to the human subject; in the cow it produces cow-pox, and in man the genuine vaccine pustule; whence it appears that the preservative of small-pox may be obtained from two sources, and not from one only, as hitherto we have generally believed.—'Journal of Practical Medicine and Surgery.'

BIRTH.

MORRIS.—On May 30, at Deddington, Oxon, the wife of John T. Morris, M.D., M.R.C.S.L., of a daughter.

DEATHS.

BRIDSON.—On the 24th ult., J. Bridson, M.D., of Hills House, Douglas, Isle of Man, aged 39.

BURGON.—On March 8th, at Sydney, New South Wales, J. Burgon, M.R.C.S.E., aged 39.

CLARK.—On the 22nd ult., G. Clark, M.R.C.S.E., of York, aged 76.

CLOUGH.—On the 20th ult., at Bawtry, Yorkshire, C. F. Clough, M.R.C.S.E., aged 30.

DAVISON.—On the 28th ult., in the Avenue de la Porte Maillot, Paris, T. Davison, M.D., aged 65.

MACLEOD.—At Huanaco, Peru, G. Macleod, M.D., son of the late J. Macleod, Surgeon, of Glasgow.

MAHONY.—On the 24th ult., J. Mahony, L.K.Q.C.P.I., of Cappoquin, Co. Waterford, Medical Officer to the Cappoquin Dispensary District of the Lismore Union, aged 26.

MASON.—On the 13th ult., at Stockton, S. Mason, Surgeon, formerly of Newcastle-upon-Tyne, aged 51.

RILEY.—On the 22nd ult., suddenly in the street, J. Riley, M.R.C.S., of Percy street, Tottenham court road, aged 62.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JUNE 8.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Fergusson, "On the Progress of Surgery during the Present Century."

THURSDAY, JUNE 9.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. J. Hullah "On Music (1600—1750)."

FRIDAY, JUNE 10.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Fergusson, "On the Progress of Surgery during the Present Century;" Royal Institution, 8 p.m.—Prof. Tyndall: "A Magnetical Experiment."

SATURDAY, JUNE 11.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.; Royal Institution, 3 p.m.—Mr. Alexander Herschel, "On Falling Stars and Meteorolites."

MONDAY, JUNE 13.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JUNE 14.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Croonian Lectures for 1864: the Significance of Dropsy. By W. R. Basham, M.D., F.R.C.P., &c. London: John Churchill and Sons, New Burlington street.

Lectures; chiefly Clinical. By Thomas King Chambers, M.D. Third Edition. London: John Churchill and Sons.

The Pharmaceutical Journal for June.

The Essentials of Materia Medica and Therapeutics. By A. B. Garrod, M.D., F.R.S. Second Edition. London: Walton and Maberly, Upper Gower street, and Ivy lane, Paternoster row.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

MR. CALLENDER, *St. Bartholomew's Hospital.*—The notices and lists have been received.

DR. JAMES TUCKER.—The subjects shall be noticed; but we fear that one of the extracts alluded to would occupy too much of our space.

MR. J. T. MORRIS.—The notice is inserted, and we regret the oversight to which allusion is made. We have ourselves no knowledge or recollection of the circumstance.

THE ROYAL INSTITUTION.—The report has been received.

X. A.—We believe the life office in question to be a highly respectable one.

MR. R. F.—The qualification is held by the Poor-law Commissioners to be equivalent to a diploma in surgery.

DR. PURVIS, *Greenwich.*—We sincerely hope that all further unpleasantness will cease between Dr. Purvis and Dr. Moon, and that both parties will especially avoid carrying on any discussion in the local newspapers. We think that there is something to be said on both sides of the question, which is, however, purely a professional one, and the merits of which the general public cannot possibly understand.

REFORMER.—The College of Physicians requires of its licentiates three years' compulsory attendanceat a medical school. The other year may be spent at a medical school, *or* an infirmary, *or* dispensary recognised by the College. The College of Surgeons recognises, in addition, a pupilage to a surgeon in general practice as a part of the professional course. The Society of Apothecaries of London invariably requires five years of professional study, including the term of attendance on lectures and hospital practice.

DR. T. L.—Valerianic acid is not obtained, in commerce, from the Valerian root, in which, however, it exists, but from fousel oil, or amylic alcohol. The valerianic acid from either source has the same chemical composition.

Just published, for 250 Cases, 2s.; 500 Cases, 3s.,

Register of Obstetric Cases.—This Form has been published under the authority of the Council of the Obstetrical Society of London.

J. Smith and Co., Medical Stationers, 52 Long acre, W.C.

Price's Glycerine, its Uses and PURITY.—See 'De la Glycerine, de ses Applications à la Chirurgie et à la Médecine,' by the eminent French Surgeon, M. Demarquay,—pp. 240. Paris: P. Asselin, 1863; or 'On Glycerine and its Uses in Medicine, Surgery, and Pharmacy,' by Dr. W. Abbotts Smith.

London: H. K. Lewis.

St. John's Hospital for Diseases of the Skin, Church street, Westminster.

PHYSICIANS.—Tilbury Fox, M.D.; J. Mill Frodsham, M.D.

SURGEONS.—Erasmus Wilson, F.R.S.; J. L. Milton.

The Medical Officers attend daily at 2 p.m. Lectures on the Pathology and Treatment of Cutaneous Diseases and Clinical Lectures are delivered during the Medical Session. The Practice of this Hospital is open to all Members of the Profession and Students of Medicine.

Partnership.—The Proprietor of a valuable Sanitarium on the South Coast, from advanced age and declining health, is desirous of receiving a Partner with a view to his own early retirement. To a single gentleman in delicate health, this would prove a desirable mode of securing a liberal income without fatigue and of forming a select private practice. 700*l.* will be required for a moiety of the household furniture, fixtures, and outlay.

Address M.D., HENRY H. HOWE, Esq., Solicitor, Victoria Street, Pimlico, S.W.

Weiss's Illustrated Catalogue, containing nearly 800 Engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price 5s.

62 Strand, London.

"This Catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced; and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour, which we are glad to see strictly observed in this Catalogue."—Vide 'The Lancet,' Sept 12th, 1863.

Anatomy, Physiology, Pathology, and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

The Medical Baths and Fumigations. 40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.

Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Baréges, Harrogate, and other Baths, constantly ready, or prepared to order.

These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible, or have altogether failed n effect. Imitations having arisen, be particular in the address.

DINNEFORD'S

Pure Fluid Magnesia, now perfect in purity and strength.

"Mr. Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.), specially adapted for the use of Medical Men and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

J. Clarke (late Thompson), Surgical Instrument Maker, Cutler, Truss and Bandage Maker, 225 Piccadilly, near Regent's Circus, W.

Lichen Islandicus, or Iceland Moss COCOA.

Strongly recommended by the Faculty.

See Testimonials of Dr. Hassall, Dr. Normandy, with others. To be had everywhere, at 1s. 4d. per lb.

Manufactured by

DUNN AND HEWITT, LONDON.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

BY ROBERT HUNTER SEMPLE, M.D.,

Member of the Royal College of Physicians of London, Senior Physician to the St. Pancras and Northern Dispensary, Physician to the Standard Life Assurance Company.

(Continued from page 328.)

The Morbid Sounds of the Heart, or Murmurs.—Endocardial Murmurs.—It has been already stated that the bellows murmur, or the allied sawing, or rasping murmur, heard over the region of the heart, indicates the presence of some morbid condition within the heart, being due either to the existence of diseased valves or of diseased blood passing over healthy valves. The diagnosis between these two conditions is by no means easy in all cases, although there are some general indications which will often assist in removing the difficulty. It is a very common occurrence for persons to present themselves to the medical practitioner complaining of palpitation of the heart, difficulty of breathing, and cough, with rapid and weak pulse, and in whom a murmur is perceptible over the cardiac region; and yet very many of such patients have no organic disease of the heart whatever, and soon lose their unfavourable symptoms under the use of tonic and chalybeate remedies and good diet. These persons are usually females, and until their cases have been fully considered, their history thoroughly investigated, and the results of treatment observed, it is occasionally impossible to form a positive opinion. The absence of any previous rheumatic attack, and the presence of evident chlorosis, and the derangement of the uterine functions, will throw light upon the diagnosis, which, however, may still be obscure. Again, even in men, in whom the existence of a murmur is less common than in women, it must not be at once concluded that the presence of this sound indicate endocardial or valvular disease, for any causes which tend to impoverish the blood may give rise to this sound and thus lead to erroneous deductions, unless all the concomitant circumstances of the case and the previous history are taken into consideration.

These morbid sounds, or murmurs, are, in fact, caused either by actual endocardial disease or by alterations in the character of the blood. Among the former class may be placed contraction of the orifices of the heart, caused by the thickening and hardening of the valves; inflammation of the endocardium, with albumino-fibrinous exudation; and growths, tumours, or vegetations, offering an obstacle to the passage of the blood; also the insufficient closure of the valves, which are thus unable to oppose the retrograde movement of the blood, abnormal adhesion of the valves to the walls of the ventricles or of the arteries, and lacerations or perforations of the valves. Among the latter class are included those cases in which a murmur is caused by chlorosis, or anæmia, the latter being either constitutional, or caused by some accidental loss of blood, or by wasting diseases which attenuate the vital fluid.

MM. Barth and Roger, in their 'Traité Pratique d'Auscultation,' lay it down as a law that the cardiac murmurs which are independent of organic disease are always connected with the first sound, and never with the second, and this observation is very good as far as it goes; but it must be remembered that, in most cases of organic disease of the heart, the cardiac murmurs, as will be hereafter shown, are also heard only in connection with the first sound. Hence, therefore, the presence of a diastolic murmur will be a pretty certain evidence of the existence of organic disease, though the converse is by no means true, that its absence indicates the affection to be due merely to morbid conditions of the blood. But the existence of a double murmur, accompanying or replacing the natural sounds of the heart, is a certain sign of organic disease.

The careful examination of the concomitant symptoms is of very great importance in distinguishing between the organic and the functional affections of the heart, and in the former there is frequently an assemblage of characteristic symptoms—such as præcordial dulness, the thrill felt on applying the hand over the region of the heart, the co-existence of pneumonia, bronchitis, or pulmonary apoplexy, the alteration in the character of the pulse, the presence of œdema of the extremities, and other signs of serious disturbance of the circulation. But still the above circumstances may be wanting, either wholly or in part, even in cases of confirmed organic disease of the heart; and some of them may be present when there is no organic disease at all. Difficulty of breathing and dropsy, for instance, may be present in chlorosis, anæmia, and exhaustive diseases, and the action of the heart may be accelerated, or excited, under the same conditions. It is also mentioned by Barth and Roger that the cardiac murmur, which is a sign of organic disease, may be very well marked without the co-existence of the murmur along the course of the carotid arteries; while in alterations of the blood there is never a well-marked murmur over the heart without the co-existence of murmurs in the vessels of the neck. These murmurs may be arterial or venous, and are often exceedingly loud—the former being intermittent and synchronous with the cardiac systole, the latter being continuous, and easily made to cease by pressure on the jugular vein *above* the point where the murmur is heard.

This observation, however, is only true to a certain extent; for in organic disease of the heart, attended with degeneration of, or vegetations upon, the cardiac valves, it very often happens that there is also atheromatous degeneration of the arterial system, which gives rise to a murmur over a great number of the arteries—the carotids in particular. I have repeatedly heard murmurs over the subclavian and carotid arteries in cases of valvular disease of the heart, and after death I have found atheromatous degeneration over the whole course of the aorta, and over many of the principal arterial trunks. I do not assert that a well-practised eye and ear and touch would not be able to distinguish with considerable facility between the sallow aspect, the loud humming and musical murmur, and the nervous irritability of the heart's motions, in functional disease on the one hand; and the congested countenance, the blowing or rasping murmur, and the peculiar vibratory thrill of the heart, in organic disease, on the other hand. But still it is only by assiduous cultivation of the senses, and by frequent practice, that these distinctions can be clearly drawn; and it is essential to point out the sources of error and the best methods of avoiding them. I should also mention that in many cases in the male subject, when no disease of the heart could be detected, I have met with a harsh, grating murmur over the arch of the aorta, the innominata, or the carotid arteries. Now, in the female subject, this murmur would be attributable, most probably, to anæmia or chlorosis, but in the cases to which I allude, I have regarded them as indicating an atheromatous condition of the large arteries proceeding from the heart, inasmuch as the subjects were not anæmiated and were not suffering from any apparent constitutional disease.

Drawing up the diagnostic differences between organic

and functional murmurs in a tabular form, the result would be somewhat as follows :—

Organic Murmurs.	*Functional Murmurs.*
1. Although often single, are sometimes double.	1. Are always single.
2. Are sometimes prolonged into the large arteries proceeding from the heart, but are never heard in the jugular veins.	2. Are almost always prolonged into the large arteries proceeding from the heart, and are often heard in the jugular veins.
3. Are often associated with hypertrophy of the heart, and consequently with increased force of the heart's action, and with a strong thrill felt by the hand.	3. Are often associated with undue excitement and irritability of the heart, but not with increased volume or with thrill.
4. Are often associated with œdema of the legs, cough, and secondary bronchitis, pneumonia, or pulmonary apoplexy.	4. Are often associated with œdema of the legs and cough, but not with bronchitis, pneumonia, or pulmonary apoplexy.
5. Are often connected with a pre-existing history of rheumatism.	5. Are unconnected with any history of rheumatism.

(To be continued.)

HOSPITAL REPORTS.

KING'S COLLEGE.

The first case operated on to-day (May 28th) was a child, who suffered from nævus of the lower lip, affecting the left half only. The tumour was of small size, and had been reduced by former operations ; in consequence of its limited dimensions, Mr. Fergusson considered that it might now be removed by means of the nitric acid, which he, therefore, applied freely around it at its peripheral margin, using for the purpose a piece of pointed wood. No chloroform was administered.

The next subject for operation was a child with cleft palate and hare-lip, the division in the latter being on the left side. The child being anæsthetised with chloroform, and the entire body and limbs swathed in the red cloth used at operations, so that the child should be completely steady, its legs and arms being thus fast bound, the nurse sat on one chair, while the operator sat upon another opposite to her ; the child was laid upon its back, with the back of its head resting between the knees of the operator. Seizing the right division of the upper lip and drawing it forwards from the gum, Mr. Fergusson proceeded to detach it from its connection ; having done the same on the left side, he then removed in his usual manner, by means of the scalpel, the tissues which formed the margins of the fissure, adopting at the lower or oral extremity of the lip the incurvation of the incision so as to adapt, without any puckering, the apposed points of the fissure. We remarked that Mr. Fergusson did not put in the lower needle first ; but in his hands, guided as they are by long and very great experience, such a manœuvre is warrantable, because practicable without any fear of future detriment to the patient ; the eye of the operator, accustomed to the most delicate apposing of structures, being capable of fully measuring any inequalities and of guiding him in bringing into the most perfect possible union those parts subjected to the operation. The two parts of the lips were united by the needles and figure of 8 suture, and were then painted over with collodion, which checked hæmorrhage, excludes the air, and tends to maintain the junction of the newly-rawed surfaces. The peculiar features of this case were : first, the fissure was a wide one ; and, secondly, there was a projection of the maxillary bone of the left side, though not of so great a prominence as to warrant its division or even bending back, the backward compressing force of the recently united lip being sufficient for the rectifying of this malformation. The patient was about six months old. This is not the period of life at which Mr. Fergusson prefers to operate ; when he can make it a matter of choice, he selects an earlier age.

The third case was a man of about middle age, of a stout habit of body, and of the sanguine temperament. But for the peculiar diathesis which led to the formation of this calculus, the health seemed to be perfect. A large staff with a good curve was first passed into the bladder to make certain of the presence of the stone ; this was withdrawn, and one of smaller size substituted, which was given into the charge of Mr. Wood. The perinæum had been shaved before the man came into the theatre. The rectum having been ascertained to be emptied, Mr. Fergusson made the superficial incision, in the course of which step the patient partially awoke from the chloroform ; and as his condition would not allow of its being pressed with him, the rest of the operation had to be accomplished under very great difficulties, owing to his restlessness and violent struggles. Notwithstanding all these obstacles, the stone was extracted with great expedition. It proved to be one of large size, and was likewise very rough on its surfaces : this latter character had in the sounding conveyed the idea that there might be a second stone present in the bladder ; but on closer visual examination of the calculus such was discovered to be an error, and exploration of the viscus, after the incision had been made into it, demonstrated the absence of any other foreign body than that which had been removed. The calculus was very hard. In this instance, lithotrity could not have been attempted; inasmuch as great irritability of the parts existed, and the using of instruments could not be tolerated, nor could the system be accustomed to their employment ; otherwise the stone might have been crushed. An additional difficulty existed in the fact of the perinæum being of unusual depth.

When this patient had been removed, Mr. Fergusson showed a man whose foot, some eighteen months previously, had been amputated by that form of operation known as Pirigoff's. The wound had quite healed ; there was no discharge, no tenderness in the stump ; and the patient walked with scarcely any perceptible halt. So complete, in fact, had the operation been performed, and so perfect was it in its results, that, with a false front extremity to the foot, no defect could be detected by the most scrutinising observer.

The last case operated on by Mr. Fergusson was one of congenitally divided soft palate, the division extending through the velum from its attachment anteriorly to the palatal bones to its termination in the point of the uvula. The steps of the proceeding were : first, the division of the levator palati with the knife peculiarly adapted to this purpose ; secondly, the removal of the margins of the cleft ; and thirdly, the bringing together of the bare, denuded surfaces, and keeping them in apposition by the aid of the silk sutures.

Mr. Wood then operated on a little boy who, some years previously, had received a severe burn of the right hand, and who, three years since, had undergone an operation for the cure of the malposition resulting from the cicatrix : the cure had not been effected and the thumb had become greatly incurvated upon the palm of the hand, so much so as to be wholly useless. As the muscles, though atrophied, were still present, it was thought that, by the performance of a plastic operation, some alteration could be produced which would render the member, at least in some measure, fit for use.

Passing the knife underneath the tense band of tissues which drew the thumb inwards toward the palm, and having brought its point out in the direction opposite to the aperture of entrance, the edge of the instrument was then turned to the tense band, which, rendered still more tense by traction, was in this manner divided. A flap was then taken from the lax integuments of the back of the hand, and brought downwards and forwards so as to cover in that portion of the palm which had been laid bare by the separation of the constricting band of the tissues involved in the cicatrix of the burn.

The apex of the integumentary flap was downwards, and the base was at the wrist, so that the arterial supply was in no way diminished, but was continued unimpaired, being

kept up, as before the operation, by the ramification of the vessels from above—that is, from the elbow toward the hand. The margins of the transposed flap were maintained in their new situation by means of the thread sutures; but before this was done, the bleeding from the denuded surfaces was checked as much as possible, and the parts carefully freed from any interposed blood: this was with the object of effecting union throughout the entire, by means of the first intention. The exposed parts of the palm of the hand, whence the flap was taken, were left to heal by granulation. Mr. Wood, in all these plastic operations, inculcates the absolute necessity, for the success of the operation, that the flap should have its base in the direction from which the branches of the arteries proceed; and he considers that one of the great sources of failure is to be found in the fact that the base is often placed in the wrong direction—that is, in such a manner as to have the vitality of the entire flap preserved merely by the recurrent or anastamotic branches of arteries. Another cause of want of success is the placing the flap in a constrained position, by which the vessels running into it, or coursing through it, are constricted. All the constricting bands which had bound down the thumb in its unnatural situation having been divided, the flap having been dissected out and transposed, and fixed in its new situation, the thumb itself was then brought into its proper position by the aid of bands of adhesive plaster, and was kept *in situ* by the same means. Over the raw surfaces, as well as over the flap, compresses of fine lint (wetted) were placed, and all was then enveloped in the folds of an ordinary roller-bandage.

The last case was one of a boy aged about sixteen years, who had been for some time the subject of flexion of the leg, upon the thigh, consequent, he said, upon an affection of the knee-joint. On examination, the knee-cap seemed fixed on the outer condyle by a species of anchylosis, either osseous or fibrous; there was also a certain amount of rigidity and contraction of the inner hamstrings, the foot was rotated outwards, and the sartorius muscle was not free from implication in the disease.

The patient was placed under chloroform, and Mr. Watson then proceeded to remove the deformity by forcibly extending the leg, which was done without very great difficulty, the tendons, and whatever adhesions were present, yielding readily in the course of the extension. The leg was subsequently placed upon a padded splint, and bound to it by means of a strong bandage.

UNIVERSITY COLLEGE HOSPITAL.

UNDER THE CARE OF MR. ERICHSEN.

We visited a patient who had been admitted some time previously for concussion of the brain, from the effects of which she was suffering at the period of her admission.

Injuries of the head may be divided into those involving the scalp, the scalp and bones, and those not alone implicating the structures we have just mentioned, but extending themselves deeper, so as to affect the membranes of the brain and the brain itself.

We shall now direct attention to the subjects—Concussion and Compression. By the former is implied a suspension of the natural actions and functions of the brain, dependent upon violence inflicted upon the cranium directly or indirectly; by the latter term, that there is a comatose condition, more or less perfect, induced by a compressive agency, either blood, bone, or the sequences of inflammation. But certain other conditions obtain besides the comatose; nor is this always complete.

There is a third condition produced by mechanical force applied to the head; it is that of cerebral irritation.

Of concussion, there are several degrees: but for all practical purposes these may be arranged under two principal heads, the first of which will comprise all the milder; while under the second we may range the severer and those having a fatal conclusion. First, then, the patient may not be at all deprived of consciousness, and there may be only a little vertigo and faintness, or he may feel an inability to walk or even to stand, attended or not, with a certain amount of nausea. Such are the symptoms that would exist in probably the mildest cases which do not, however, generally present themselves to the medical practitioner.

The next condition we would portray is that in which we find our patient lying at full length, stretched upon his back and motionless; the face pale and somewhat ghastly; the entire surface cold and blanched, harsh, rough, and rather dry; the breathing tranquil and natural; the pulse small, thready, irregular, feeble, or even intermittent. The state of the pulse is always very much influenced by the amount of unconsciousness; the pupils are very frequently contracted, though they vary very much in respect of the extent of their dilatation, their dilatability, and their response to the stimulus of light, the variation being likewise dependent upon the degree of force applied and the degree of shock sustained. There may be a semi-consciousness—that is, the patient can, when shaken and addressed in a loud voice, be aroused from his lethargy, made to understand and answer questions (which he does in a peevish, pettish manner, as he turns himself away from his interrogator); after which he will quickly lapse into the partial unconsciousness. The muscles, though not actually paralysed, are rendered feeble and flaccid, and the limbs are, in some instances, moved about as they might be in unquiet sleep; the sphincters, sharing in the general muscular prostration, will prove inefficient in their action, so that the fæces and urine will escape involuntarily.

And now, at this stage of the symptoms, will come the crisis. If the case should tend to an unfavourable issue, the symptoms we have above described will become aggravated in their character; the insensibility will become more profound and continuous; the nervous and muscular prostration more complete; the circulation, so feeble that the pulse can scarcely be felt; the eyes glassy; the skin cold; the features pinched; the pupils contracted or dilated to the extreme. In this moribund condition the patient may continue for some hours, when at length all the symptoms will be stayed in death.

If recovery be about to supervene after the crisis has passed away, the vomiting, which so often occurs in favourable cases, will have awoke the patient from his unconsciousness, excited not alone the languid circulation, but all the dormant energies, and will have proved, in fact, a general excitant or stimulant. The act of vomiting is in itself one of the most happy and encouraging symptoms, inasmuch as it shows that the system is alive to the injury.

The evidences of recovery will now manifest themselves: the heart's action becomes stronger; the pulse fuller; the surface soft and moist; the eyes less and less glazed; the features less pinched and altered, till they resume their wonted expression; the stupor less profound, until at length the brain regains its normal action, its supply of blood having been increased and sent to it with greater regularity.

The sequelæ of concussion may be: headache, varying in its intensity, being sometimes of a trivial nature, at other times of a most severe type; and unless the greatest caution be observed, that would quickly merge into the cephalalgia arising from inflammation of the brain or its membranes; vertigo; loss of memory; incapacity for mental work, or even for thinking; loss or impairment of one or more of the senses, more particularly of the power of hearing and smelling; irritability of temper and an inability to govern it.

The brain is in many instances rendered so excitable as to unfit the person for any employment in which the mind is called into undue action; and for the same reason the use of stimulants must be avoided. These conditions may exist for some time, and, as they continue, they will tend to weaken and exhaust the system the more, till *sudden* death terminates the sufferings. Strabismus, paralysis of the lids, amaurosis, loss of the virile power or of the muscular strength generally, priapism, irregularities of vision, a preternaturally slow pulse, may, one or more of them, be present as sequences of the lesion; but concussion may result in compression, or, owing to a too great

reaction, inflammation of the brain, or its coverings may be lighted up.

The pathological changes may in a number of instances be not at all traceable; but that certain changes *are* effected is indubitable, from the set of symptoms which succeed to the injury. Sometimes a peculiar appearance of the brain is found at the post-mortem examination; it is as though the interior of the organ were besprinkled with cayenne pepper. This was especially pointed out by Dr. Bright, and is to be observed when the horizontal section is made. It is dependent upon an over-filled and congested state of the vessels and some ecchymosis. If the injury be inflicted suddenly, the shock will be very much more severely felt than if it be inflicted slowly and even very much more violently. If the shock be very violent, the heart's action may be stopped immediately.

We now pass on to compression of the brain. This condition may be produced from depression of the bone; from the effusion of blood between the calvarium and the dura mater; between the meninges of the brain, or between the brain itself and its meninges; from the formation of pus within the cranium; or from the presence of some foreign body. The symptoms are pretty generally as follow, no matter what may be the immediate cause of them: coma, more or less complete—if there be only semi-unconsciousness, the patient may be roused by being shaken or spoken to in a loud tone of voice; paralysis, either general or partial; surface of the body cool, or warm, or even hot, moist, or perspiring; pupil sluggish in its action or dilated and insensible—one may be dilated, and the other either of its natural size or contracted; the respiration slow, deep, stertorous, and whiffy.

The stertor arises from paralysis of the velum pendulum palati, and the whiffiness in breathing from the same condition of the buccinator muscles. The urine is at first retained in the bladder because the detrusor muscle is affected in the same manner as the buccinator; but as the viscus is distended with its peculiar fluid, this latter flows away involuntarily, constituting that condition known under the name of "Stillicidium."

The character of the urine may be altered: it may become ammoniacal, or loaded with lithates or with phosphates, or it may contain even sugar. This last is the product of irritation or unusual disturbance at the base of the brain, more especially at the origin of the pneumogastric nerve. The fæces will be passed under the patient and wholly involuntarily. The coma may not be continuous, but alternate with delirium or a wakefulness, attended with a spastic condition of the muscles of one or other parts of the body. These last are symptomatic of cerebral irritation, and are not infrequently found to obtain where the membranes of the brain are lacerated.

It is hardly necessary to allude to a complication we may sometimes find in cases of compression; it is, inflammation of the brain or its coverings, or of both together. Unless the compressing agency be removed, this inflammation will run a very speedily fatal course, the person dying as though from an apoplectic seizure.

The symptoms of cerebral irritation are: first, those affecting the mind; and, secondly, those in which the body is chiefly concerned.

THE INSANE SCATTERED IN VILLAGES.—In the department of the Rhône (France), the authorities have decided that the insane and harmless paupers shall be placed with respectable country people on account of the great crowding of the asylums. It is expected that open-air life and plenty of healthful occupation will be extremely beneficial to the patients.

A WISE MEASURE IN PARIS. — A committee appointed by the municipal authorities is now visiting all the parish schools and refuges, so as to ascertain whether these establishments are organized with due regard to the health of the children. Public schools will likewise shortly be inspected.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XVIII.

ATROPIA.—This alkaloid and its sulphate were contained in the last London Pharmacopœia, but the atropia was only described in the Materia Medica, no process being given for its preparation. In the British Pharmacopœia the sulphate is omitted, but the alkaloid itself is described, and a process for obtaining it is also given.

The process is somewhat complicated to describe in detail. It consists essentially in preparing a tincture of belladonna root, agitating this with a little slaked lime, filtering, slightly acidulating the filtrate with sulphuric acid and evaporating it to one-fourth, or adding some water and again evaporating to one-third; then treating the residual liquid with carbonate of potash and shaking it with chloroform. The chloroform, holding the atropia in solution, is separated from the supernatant liquid and distilled to dryness. The residue is purified by re-solution in spirit and treatment with animal charcoal.

Atropia, when pure, occurs in the form of white silky prismatic crystals, which possess a bitter, nauseous taste. It is sparingly soluble in water, more so in ether, and still more so in alcohol and chloroform. Its aqueous solution exerts an alkaline reaction on litmus, and gives a bright, yellow precipitate with chloride of gold. Atropia may also be to a certain extent recognised by its power of dilating the pupil of the eye. The tests for its purity given in the Pharmacopœia are its entire solubility in ether, and the absence of ash when burned in the air.

Atropia exists in all parts of the belladonna plant, and may be readily extracted from the expressed juice of the fresh herb by means of chloroform. It also appears to be identical in its nature and composition with the crystalline principle obtained from the seeds of the *Datura stramonium*, and which was first named *Daturia*.

The composition of atropia has been accurately determined by Liebig and by Von Planta. It is $C_{34}H_{23}NO_6$, which is the formula given by the Pharmacopœia. There are two preparations of atropia now officinal—a liquor and an ointment. The liquor is prepared by dissolving four grains of the alkaloid in seven drachms of water and one drachm of rectified spirit. The ointment is obtained by dissolving eight grains of atropia in half a drachm of spirit, and then mixing with one ounce of lard.

BEBERIÆ SULPHAS.—This alkaloid is for the first time introduced into the Pharmacopœia. It is obtained from the Bebeeru bark which is yielded by the Greenheart-tree, a native of British Guiana. The wood is largely imported into this country, and used in shipbuilding. The tree is a species of laurel and belongs to the genus Nectandra. It has been named the *Nectandra Rodiei*, because Mr. Rodie, a navy surgeon, was the first to point out the peculiar febrifuge properties of its bark. Dr. Warburg's vegetable fever drops are said to be prepared from the fruit of this tree. The bark some time back attained considerable notoriety as a tonic, antiperiodic, and febrifuge; and it has been thought by some that the alkaloid bebeerine would constitute a valuable substitute for quinine.

Nectandra, or Bebeeru bark, is described in the Materia Medica as occurring in large flat heavy pieces from one to two feet long, from two to six inches broad, and about a quarter of an inch thick. External colour, greyish brown; internal, dark cinnamon-brown. Taste, strongly and persistently bitter, with considerable astringency. It is only ordered for the preparation of the sulphate of beberia.

There is considerable difficulty in preparing the salts of beberia, arising principally from the circumstance that the alkaloid and its salts are uncrystallizable. The process

given in the Pharmacopœia involves numerous details, which are essential to success, but tedious to describe. It consists essentially in exhausting the powdered bark by dilute sulphuric acid, concentrating the solution and precipitating by ammonia—exhausting the precipitate when washed and dried with spirit, evaporating the spirituous solution, and then carefully neutralising it with dilute sulphuric acid. The solution of sulphate of beberia so obtained is evaporated to a syrup, and spread on glass plates to dry.

Sulphate of beberia so obtained is in the form of thin translucent scales of a dark brown colour, appearing yellow when powdered. Its aqueous solution gives with caustic soda a yellowish white precipitate, which is dissolved by agitating the mixture with twice its volume of ether. The etherial solution, separated by a pipette and evaporated, leaves a yellow translucent residue, entirely soluble in dilute acids.

When this alkaloid was first examined, it was stated to have the same atomic composition as morphia; a more recent investigation, however, by Von Planta has shown this to be an error. The formula for the sulphate given by the Pharmacopœia is the one indicated by Von Planta; it is, $C_{38}\ H_{21}, N\ O_6, H\ O, S\ O_3$.

The dose of sulphate of beberia is stated to be one to three grains as a tonic, and five to twenty-five grains as a febrifuge.

BISMUTHUM ALBUM.—Following the example of the Edinburgh College, the compilers of the British Pharmacopœia have given the name "white bismuth" to the nitrate of bismuth of the London College. In so doing, they have undoubtedly adopted the most unscientific and the most indefinite of the many names which have been bestowed on this preparation. Failure has certainly attended many of the attempts to name this compound in accordance with the usual principles of chemical nomenclature. Nitrate, tetartonitrate, and trisnitrate have all proved exceptionable.

The name employed by the Dublin College, however—*i. e.*, subnitrate of bismuth—appears free from all objection, and we cannot but regret that it has not been adopted in the British Pharmacopœia.

To prepare white bismuth, according to the process now given, two ounces of coarsely powdered metallic bismuth are to be disolved in 2½ oz. nitric acid and 3 oz. of water.

During this part of the process a ter-nitrate of bismuth is formed, according to the following equation:—

$$Bi + 4\ No_5 = Bi\ O_3\ 3\ No_5 + No_2.$$

When effervesence has ceased, heat is to be applied for ten minutes, and the liquid decanted from any undissolved particles. The solution is to be evaporated to two ounces and then poured into half a gallon of water. When the precipitate has subsided, the supernatant liquid is to be poured off, and a fresh half-gallon of water added. Lastly, the precipitate is to be drained and dried at 212°.

When the solution of nitrate of bismuth, produced as described, is poured into a large quantity of cold water, a decomposition occurs in which the water takes a large portion of the nitric acid of the salt, while oxide of bismuth is precipitated, still retaining a portion of the nitric acid. The liquid which is poured off contains a large quantity of free nitric acid, holding a little nitrate of bismuth in solution, while the precipitate contains some nitric acid combined with a relatively large quantity of oxide of bismuth. The proportion of the acid to the oxide, however, is liable to considerable variation and is greatly influenced by the amount or duration of the washing the precipitate is subjected to. Fresh water removes more acid from the compound, and thus alters its composition. Dr. Edwards has shown that the proportion of nitric acid actually varies from 3 to 18 per cent. To ensure, as far as possible, uniformity in the product, it is essential to follow rigidly the proportions indicated in the process.

The inconvenience of employing chemical formulæ in a Pharmacopœia is again evidenced by this preparation. It is represented as $Bi\ O_3, NO_5$.

The tests given for the purity of white bismuth are, that it dissolves in nitric acid without effervescence, and that its solution gives no precipitate with dilute sulphuric acid.

REVIEW OF BOOKS.

Lectures on the Elements of Comparative Anatomy. By Thomas Henry Huxley, F.R.S., Professor of Natural History, Royal School of Mines; and Professor of Comparative Anatomy and Physiology to the Royal College of Surgeons of England. *On the Classification of Animals and on the Vertebrate Skull.* 8vo. pp. 303. London: Churchill and Sons. 1864.

Handbuch der Zoologie. Von Wilh. C. H. Peters, Prof. der Zoologie und Director des Kön. Zoolog. Museums in Berlin; Jul. Victor Carus, Prof. der vergleichenden Anatomie in Leipzig; und C. E. Adolph Gerstaecker, Docent der Zoologie an der Universität zu Berlin. Zweiter Band. *Arthropoden*, bearbeitet von A. Gerstaecker. Pp. 642. Leipzig, 1863.

(*Manual of Zoology.* By Wilhelm C. H. Peters, Professor of Zoology and Director of the Royal Zoological Museum of Berlin; Julius Victor Carus, Professor of Comparative Anatomy at Leipsic; and C. E. Adolph Gerstäcker, Teacher of Zoology in the University of Berlin. Second volume, Arthropoden. Edited by A. Gerstäcker. Pp. 642. Leipsic, 1863.)

(Continued from page 380.)

The third lecture treats of the ECHINODERMATA, SCOLECIDA, ANNELIDA, CRUSTACEA, ARACHNIDA, MYRIAPODA, and INSECTA. The first group in this list, the ECHINODERMATA, comprises the star-fishes, sea-urchins, sea-cucumbers, feather-stars, &c., marine animals which, while differing extremely in outward appearance, present a more or less definite radiate appearance, and hence were included by Cuvier in the RADIATA. The most remarkable character of the *Echinodermata* "is the nature of the embryo and the strange character of the process by which the adult form is originated, by a secondary development, within that embryo;" in the larval state (with possibly one or two apparent exceptions), there is no trace of radial symmetry, the young echinoderm exhibiting as complete a bilateral symmetry as annelids or insects. These remarkable metamorphoses were first noticed by the great German physiologist, Professor Müller, and were described by him in seven memoirs "On the Larvæ and Metamorphoses of the Echinodermata," that appeared in the 'Abhandl. d. Berlin. Akad.,' between the years 1846 and 1854; but they were little known in this country until Professor Huxley published, in the 'Annals of Natural History' for 1851, an admirable *résumé* of Müller's labours as far as they had then extended. The second group, the SCOLECIDA, has given naturalists more trouble than any other. Professor Huxley makes it include the *Rotifera* (or wheel-animacules), the *Turbellaria*, the *Trematoda* (or flukes), the *Tæniada* (or tapeworms), the *Nematoidea* (or threadworms), the *Acanthocephala*, and the *Gordiacea*. Of these, all but two—the *Rotifera* and *Turbellaria*—are parasitic. The principal bond of union between the members of this group is, that the first four have been proved to possess what is termed a *water-vascular system*—a remarkable set of vessels which communicate with the exterior by means of one or more apertures situated upon the surface of the body, and branch out more or less extensively into its substance; while there are good analogical grounds for suspecting the existence of this system in the remaining three. Some idea of the difficulty of classifying this group may be inferred from the fact that the *Rotifera*, after being placed amongst the *Entomostraca* (an order of minute crustaceans) by Nitzch and Bory de St. Vincent, were removed to the *Infusoria* by Ehrenberg and Dujardin. From this decidedly false position they were rescued by Wiegmann, Milne Edwards, Siebold, Vogt, and Leuckart, who placed them among the *Vermes;* whilst Burmeister and Leydig are in favour of sending them back to the crustaceans. Siebold observes that "they differ widely from the crustaceans" ('Com-

parative Anatomy of the Invertebrata,' translated by Burnett, p. 141), and has brought forward strong anatomical arguments in favour of his opinion. Owen remarks that they "are more nearly related to the lower *Crustacea* than they are to the *Echinodermata*" ('Lectures on the Comparative Anatomy and Physiology of the Invertebrate Animals,' 2nd Edition, p. 15). Victor Carus, one of the contributors to the German work on zoology, whose title stands at the head of this article, and one of the highest continental authorities on the anatomy of the *Invertebrata*, places them in a supplement to the *Arthropoda*, without, however, believing that they belong to the *Entomostraca;* while Professor Huxley, in a subsequent lecture, proposes that the *Scolecida* (including, of course, these vagrant *Rotifera*) should, together with the *Echinodermata*, find a home in the *Annuloida*, which he now regards as a distinct primary division of the animal kingdom, and not as a subdivision of the *Annulosa*. After leaving these unsatisfactory *Scolecida*, our author passes on to the ANNELIDA, a class of large extent, containing the leech, the earth-worm, the lob-worm, the sea-worm, and the *Serpula*, one of the most common and beautiful inhabitants of our marine aquaria. The following are the chief points in which they differ from the succeeding classes:—(1) Although the body is often divided into segments (each of which corresponds with a single pair of ganglia, which are arranged nearly as in the crustaceans), and each segment may be provided with a pair of lateral appendages, these appendages are never articulated, and are never so modified as to be converted into organs of mastication. (2) No annelid ever possesses a heart comparable to the heart of a crustacean or insect, but a system of vessels with more or less contractile walls, and containing a clear red or green fluid, is commonly observed, which has been termed the "pseudo-hæmal" system, and sends prolongations to the respiratory organs. (3) The embryos of annelids are very generally ciliated, and cilia are almost invariably developed in some part or other of their organism. The last four groups of the invertebrata—viz., the CRUSTACEA, ARACHNIDA, MYRIAPODA, and INSECTA, are better known to the majority of our readers than those which have been previously noticed, and may be passed over without comment, except that we may incidentally remark that a word of explanation as to what was meant by a "Telson" and an "Oostegite" (see fig. 25), would probably have not been out of place in these days when it is the fashion to decry the study of the Greek language. Some twenty years ago a medical student of fair ability confidentially asked us, at about the close of his first winter session, whereabouts the human gizzard was. He is now doing an excellent general practice, and has the character of being rather addicted to science than otherwise. If by any unhappy chance he falls on these lectures, he will doubtless make anxious inquiry of us regarding the position and functions of his "Telson," and we regret to say that we do not know of any readily accessible source of information to which to refer him.

Passing over the fourth lecture, which treats of the classification of the VERTEBRATA, we arrive at what we consider the most important lecture in the series—that, namely, in which the arrangement of the classes into larger groups is discussed. Mammals, birds, reptiles, amphibians, and fishes present so many points of resemblance to one another, and have so many points of difference from all other animals, that, by universal consent, they are admitted to form the group of VERTEBRATA, which takes its place as one of the primary divisions, or "sub-kingdoms," of the animal kingdom.

Most zoologists regard the four classes of *Insecta*, *Myriapoda*, *Arachnida*, and *Crustacea* as forming a division to which the terms ARTICULATA and ARTHROPODA have been applied, the latter being now usually regarded as the better appellation. Considering the close resemblance between the arrangement of the nervous system which exists in the ARTHROPODA and ANNELIDA, Professor Huxley proposes that, although in most other respects they differ widely from each other, they should be associated into one great division, or "sub-kingdom," of ANNULOSA; while the *Echinodermata* and *Scolecida* are placed in a small sub-kingdom of their own, to which the term ANNULOIDA is applied. He throws the *Cephalopoda*, *Pteropoda*, *Pulmogasteropoda*, and *Branchiogasteropoda* into a group, to which he assigns the name of *Odontophora*, in consequence of their all possessing that remarkable buccal apparatus, the odontophore, which we have already described. The *Odontophora* and *Lamellibranchiata* constitute the sub-kingdom MOLLUSCA; while the *Ascidioida*, *Brachiopoda*, and *Polyzoa* differ so widely from the higher molluscs, and present so many features in common, that it is better to regard them under the title of MOLLUSCOIDA, as forming a separate division of the animal kingdom, than to make them a mere appendage to the former. The next two classes—the *Actinozoa* and *Hydrozoa*—constitute one of the most natural divisions of the animal kingdom, to which the term CŒLENTERATA, first suggested (in 1847) by Frey and Leuckart, is now almost universally applied. To those who desire to become acquainted with the structure and classification of these animals, we can strongly recommend Professor Greene's 'Manual of the Sub-kingdom Cœlenterata,' as containing an admirable *résumé* of our knowledge in this department of zoology. There now only remain the groups of *Infusoria*, *Spongida*, *Rhizopoda*, and *Gregarinida*, and these are usually associated into the sub-kingdom PROTOZOA. Professor Huxley, however, confines the term PROTOZOA to the last three groups, and raises the INFUSORIA to a separate sub-kingdom, mainly on account of their analogies with the lower ANNULOIDA.

In conclusion, he sums up his results by stating that, "in the present state of our knowledge, the whole animal kingdom is divisible into eight primary categories or groups, no two of which are susceptible, in the present state of knowledge, of being defined by characters which shall be at once common and diagnostic."

These groups are the—

VERTEBRATA.

MOLLUSCA.	ANNULOSA.
MOLLUSCOIDA.	ANNULOIDA.
CŒLENTERATA.	INFUSORIA.

PROTOZOA.

Those of our readers who studied their natural history fifteen or twenty years ago will be especially struck with the fact that Cuvier's sub-kingdom RADIATA no longer exists. The *Polyzoa* have been assigned to the MOLLUSCOIDA, the *Actinozoa* and *Hydrozoa* now constitute the CŒLENTERATA, the *Scolecida* and *Echinodermata* are now to be found amongst the ANNULOIDA, while the lowest members of the RADIATA, the *Infusoria*, *Rhizopoda*, &c., have been raised by Siebold and his school into the sub-kingdom of the PROTOZOA, at which Professor Huxley is now throwing the first stone.

This work will deservedly add to the author's high reputation. It is not altogether the book to place in the hands of a mere anatomical tyro, with the hope that he will derive from it any systematic information on the elementary principles of comparative anatomy, but it should be carefully studied by everyone who has mastered the elements of that science, and especially by every teacher in this department of knowledge. The non-complimentary remarks on Professor Owen are comparatively few, and the pugnacity for which Professor Huxley enjoys so high a character shows itself less unpleasantly than we anticipated; but a foot-note to p. 89 indicates that a great battle—greater, probably, than those regarding "the posterior horn of the lateral ventricle" and "the hippocampus minor"—is shortly to be fought in favour of a *corpus callosum* in the non-placental mammals.

Lectures on the Diseases of Women. By Charles West, M.D., F.R.C.P., Examiner in Midwifery to the University of London. Third Edition, pp. 687. London: Churchill and Sons. 1864.

The diligence with which the diseases of women are studied in the present day is abundantly proved by the numerous works which exist upon the subject, and among them that of Dr. West has long held a conspicuous position. The author belongs to the cautious rather than the speculative

order of practitioners and writers; and while many of his contemporaries have distinguished themselves for the boldness of their views, or the daring nature of their operations, Dr. West has rather shown himself the friend of conservatism than of innovation in obstetric science and practice. Thus, in the perusal of his pages, the student or the practitioner is in no danger of being led away by rash theories, or being recommended to resort to brilliant, though dangerous feats in practice; he will rather learn to doubt the value of any theory until its truth has been satisfactorily proved, and to question the expediency of an operation until its success has been completely tested. The present edition of this work does not materially differ from those which have preceded it, but Dr. West has availed himself of the current literature of obstetrical medicine, to make such alterations and modifications of his views as seem to be warranted by the circumstances of the time. On the subject of the so-called inflammation and ulceration of the os and cervix uteri, he maintains his former opinion as to the comparatively unimportant character of the conditions so named, and in this opinion he is confirmed by the recently published views of Scanzoni. He has considerably amplified the chapter relating to uterine hæmatocele; and on the subject of ovarian disease, he frankly admits that his views have undergone a considerable change, and that he now regards the operation of ovariotomy as justifiable and advisable in many cases, and as one of the legitimate proceedings of modern surgery. He gives, however, a summary of the indications and contra-indications for the operation, and advises that its perils should be fully explained to the patient before it is undertaken.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

The number commences with the first of the course of lectures now in progress of delivery at the College of Surgeons of England by Professor FERGUSSON, "On the Progress of Anatomy and Surgery during the Present Century." The very same lecture is reported in the present number of the 'Medical Times and Gazette' and we have given an abstract of it elsewhere. The following sketch of Mr. Liston, the late eminent surgeon, will be appreciated by those who were acquainted with that gentleman:—

"Mr. Liston's fame at this date (1825), particularly as an operator, was well-nigh as great as at any period of his comparatively short but brilliant career. In after-years his soundness as a pathologist became more conspicuous; and the numerous valuable preparations in the museum of this College which formed part of his collection bear ample testimony to the greatness of his doings in practical surgery. Both he and Mr. Syme had already published those remarkable essays on Amputation which, with the example set by their practice, went far to give that development to the flap operation since attained. Many circumstances contributed to give Mr. Liston early fame in Scotland. A well-developed frame, a broad forehead, a strongly-marked, handsome countenance, indicative of great courage and decision, and an eye of piercing brilliancy and great expression, at once impressed those who sought his aid with a conviction of his powers. With these were associated a hand alike marvellous for its great size, its silent expressiveness, its vigorous firmness, its lightness, and its dexterity. It was aptly said of it by a distinguished lay contemporary and admirer, the late Lord Robertson—'If hard as iron and true as steel in the theatre of operation, it is soft as thistle-down when applied to the throbbing pulse or aching brow.' The remembrance of that hand is still fresh on my memory.

"Some early operations of great magnitude and comparative novelty, aided by a certain amount of jealous opposition which merit is sure to call forth, brought Mr. Liston's fame impressively before the public; and among his achievements may be mentioned the successful removal of a scrotal tumour of more than forty pounds' weight—the first operation of the kind ever performed in this country—and successful ligature of the subclavian, which had been essayed in vain by Ramsden and others in Britain.

"When personal recollections have passed away, there will remain much to associate Mr. Liston's name with surgery, but the greatest features of his teaching powers will be forgotten. With less than average facility of speech, he had a manner in all that he did before his pupils that produced the deepest impression; and there was a style in his operations which has had more influence in this department among a large number of pupils than has been produced, as far as I can make out, by any other man in the history of surgery. Only those who have seen him can thoroughly appreciate what I now say."

Mr. HOLMES COOTE gives a brief report of "Two Cases of Partial Paralysis of Muscles of the Leg, attended with Talipes Equinus, in Infants, resulting from Measles." The nature of the cases consisted in a lesion of the spinal cord, or of its membranes, during the course of the eruptive disease. The progress of the affection is marked by the increasing disparity between the two limbs. The treatment consists in attention to the general health, attempts to maintain the circulation of the limb by the aid of warmth, friction, and electricity, and finally by bringing the raised heel to the ground by means of tenotomy, the use of Scarpa's shoe, and the employment of irons.——Mr. G. CRITCHETT gives "A Description of a New Instrument for the Extraction of Cataract;" he names the instrument the "vectis spoon," from the spoon-like form of its end, and its use in bringing away the cataract. It is not adapted for soft cataracts, but in the case of all varieties of hard ones, in which the linear extraction (after the manner proposed by Schüft, of Berlin) is performed, this instrument appears to be both safe and easy in its manipulation. It is passed behind the cataract, and when it begins to be withdrawn, it slightly imbeds itself in its substance, and *draws* the cataract (hence the name vectis) through the corneal opening.——Dr. CHARLES EDWARDS, in a short contribution to the science of surgery, relates "A Case of Sero-sanguineous Cystic Tumour of the Thyroid Gland." The tumour was very large, measuring from above downwards nine inches and a half, and ten and a half transversely. The tumour was first examined by an exploring needle, and then a trocar was introduced, by which about twenty ounces of coffee-coloured fluid were drawn off, and tincture of iodine was injected into the cyst. Symptoms of iodism were produced, but subsequently the tumour was very much reduced in size.

THE 'MEDICAL TIMES AND GAZETTE.'

The present number contains the opening lecture of Professor FERGUSSON, upon "The Progress of Surgery during the Present Century." The entire course of lectures—only six in number—will be devoted to the elucidation of this subject; Mr. Fergusson has, therefore, thought it preferable to "select several subjects in which he has taken special interest, and had peculiar opportunities, and to lay them before his hearers in such a way as to give novelty and attraction." Reference is made to "the period of calm' which prevailed about the year 1825, but

(Continued at page 400.)

THE MEDICAL CIRCULAR.

WEDNESDAY, JUNE 15, 1864.

A PROSECUTION BY THE COMMISSIONERS IN LUNACY.

It appears that a Mrs. Sophia Leander is the principal or the manager of an establishment at Chiswick, entitled The Ladies' Institution of the United Kingdom for Females of Weak Intellect. From the published reports of the proceedings from year to year, we learn that it was established in 1855, that it is designed for the benefit of the industrial classes, that it is partly self-supporting and partly sustained by charitable contributions, and that it is entirely under the government of ladies. The class of maladies for which the regimen of the institution is intended is not very clearly defined; but, from what we learn from authentic sources, it seems that it has been found available for cases which would be excluded from an hospital, and would be unsuited for, or inadmissible at, a lunatic asylum. The chief inmates of the establishment, in fact, are those poor unfortunate children (in this particular instance, of the female sex) who have been the subjects of epileptic and paralytic seizures, and who, without any hereditary predisposition to insanity, have been retarded in their intellectual development by one or other of the cruel and mysterious maladies to which we allude. It need scarcely be said that these poor creatures, the number of whom, unhappily, is daily increasing among us, and for whose cure the powers of medicine are too often invoked in vain, are scarcely to be considered insane in the real sense of that word. It is true, as we have just stated, that, from the repetition of epileptic shocks or the exhaustion of nervous power, the intellectual faculties are often blunted, and the ordinary work of education is necessarily arrested, but still these poor children are capable of considerable enjoyment, in spite of their affliction, and they may be said to be never dangerous to anyone but themselves—the chief peril, in fact, arising from the nature of the disease itself, which requires constant care and supervision. We only appeal to everybody's melancholy experience in stating that no classes of society are exempt from the visitations of epilepsy among their offspring; and while the rich are enabled to make ample provision for the care of such cases, and the poor resort to the shelter of the workhouse, there is absolutely no definite course available for the middle classes whose children may be subject to this visitation. They cannot avail themselves of the charity doled out to paupers, they may be unwilling to send their children to lunatic asylums, they may be unable to provide sufficient superintendence and accommodation at home. For such persons, an institution like that superintended by Mrs. Leander seems especially well suited, as it offers the advantages of an airy and salubrious situation, kind treatment, and watchful care.

It may be stated at once that no complaint has ever been made against the establishment, the parents or friends of the unfortunate inmates seem to have been perfectly well satisfied with the treatment adopted, and a large number of voluntary contributions to the funds of the institution has been received from all parts of the country; but the Commissioners in Lunacy have visited the house, and have indicted Mrs. Leander at the Central Criminal Court for a misdemeanour, in receiving lunatics without having taken out a licence. The evidence was very short, and of a purely technical character; no accusations of misconduct were made against any official of the establishment; it did not transpire that any of the inmates had ever injured anybody, or that any complaints had ever been made against the house or the manner in which it was conducted. One medical witness was called to prove that, in his opinion, some of the inmates were insane, and Mrs. Leander, through her counsel, declared that they were not; and eventually the jury returned a verdict of "Guilty."

We do not allege that the Commissioners in Lunacy have conducted the prosecution in a harsh or vindictive manner. Notwithstanding the verdict of "Guilty," no punishment was inflicted and none was asked for, the defendant being only required to enter into her own recognizances to appear for judgment if she should be ordered to do so. It was understood, however, that she was to comply with the orders or directions of the Commissioners as to the future conduct of the establishment over which she presides, and it was even stated that they would compel her to close it altogether.

In a mere dry and legal sense, Mrs. Leander is no doubt guilty, inasmuch as a competent witness has sworn that some of the unfortunate inmates of her establishment are not in a healthy condition of intellect; but if, in the absence of any charge of mismanagement, the middle or lower classes of society are to be prevented from sending their epileptic children to an institution such as that at Chiswick, and are to be compelled, at great expense, and at a painful sacrifice of feeling, to drive them into lunatic asylums, will not a great wrong be inflicted upon the public? In the present instance, it is possible that sufficient care has not been taken to select the cases; but still, if our information is correct, the deficiency or perversion of intellect described as existing in some of the patients is entirely due to the paroxysmal outbreaks of disease of the nervous system, and, although it may be legally regarded as insanity, it can be comprehended in that term only in the same sense as a case of fever, or of a mechanical injury to the head, or of certain kinds of indigestion, or of some peculiar forms of puerperal disease.

If then, to these well-known instances in which intellectual disturbance is known to occur, cases of infantile epilepsy or paralysis are to be added, and all such cases are to be ranked as lunatics and consigned to lunatic asylums, then indeed the class of lunatics will be enormously augmented in number, and hardly a family in the great European commonwealth will escape the reproach of being infected with the taint of insanity. Some cases of

epilepsy, it is true, are slight, and others are severe ; some are transient in their nature, others chronic ; some speedily terminate in death ; some result in sudden and unexpected recovery. In all, however, the intellectual faculties are more or less impaired, and it would be a matter of surpassing difficulty to draw the line between the sane and the insane.

But while thus drawing attention to the late prosecution, which is of far greater importance to society than the public are aware, and while giving full credit to the Commissioners in Lunacy for their zeal in doing what they conceive to be their duty, we cannot but observe that, while they are seeking to drive poor harmless epileptic or paralytic children into the lunatic asylums, they seem entirely powerless in controlling those dreadful cases of homicidal insanity which are daily causing consternation, and which are filling the obituary with murders and suicides. Not long ago, the metropolis was startled with a tale of horror, in which a man, his wife, and two children were all simultaneously sacrificed by the former ; and only last week a poor homicidal maniac murdered his own brother in cold blood. It turned out that in both these cases continual representations were made by the relatives as to the dangers which threatened them, but the warnings and the supplications of the helpless victims were unheeded. The wretched men were both *apparently* well, as far as society could tell, and the Commissioners in Lunacy, if they had been appealed to, would, no doubt, have declined to interfere. But a crusade against a few feeble epileptics is a safe game, which gives the Commissioners very little trouble, and can involve them in no responsibility.

SUMMARY OF THE WEEK.

THE ELECTION OF COUNCILLORS AT THE COLLEGE OF SURGEONS.

The excitement in reference to the choice of councillors at the College of Surgeons appears to increase as the day of election approaches. There are three vacancies, caused by the death of Mr. Green and the retirement, in rotation, of Mr. Gulliver and Mr. Hancock, both of the latter of whom, however, offer themselves for re-election, Mr. Gulliver having served the whole term of his office, but Mr. Hancock having served only one year. An attempt is again to be made to return a provincial member to the Council, and Mr. Turner, of Manchester, is to be put forward by the country party, who might succeed in returning him if they mustered in sufficient numbers. Mr. Curling and Mr. Le Gros Clark will receive great support from the London Fellows, and both are quite worthy of the distinction which their friends propose to confer upon them. Mr. McWhinnie, it is said, will also offer himself as a candidate, having arrived at the period of seniority when he is justified by usage in seeking the suffrages of the Fellows. Mr. McWhinnie was long connected with St. Bartholomew's Hospital, where he filled several important posts with great credit to himself and satisfaction to the students of that institution.

REMOVAL OF THE SITE OF THE GLASGOW UNIVERSITY.

Those who have seen the metamorphoses effected in the streets and buildings of our own metropolis by the extension of railways will hardly be astonished to learn that the venerable pile constituting the University of Glasgow has been purchased by a railway company, and that the site of the University is to be removed from the centre of the city of Glasgow to the suburbs. That this change will shock many of those who look with almost a superstitious regard upon the dark and somewhat gloomy edifice where they imbibed the elements of knowledge is very probable ; but there is no doubt that the change will be for the better, and that a new and more spacious structure, away from the city, will more adequately represent the dignity of science than the present obscure and time-worn walls. The new site has been bought by the University authorities in a beautiful piece of ground at some distance, and we congratulate our Glasgow friends on the prospect of the new College, which will rise like a phœnix from the ruins of the old one, and is, we venture to hope, destined not only to perpetuate, but to enhance the prosperity of the University.

THE CASE OF STONE *v.* STONE AND APPLETON.

About a year since we commented upon this remarkable case in the Divorce Court, where the petitioner sought for a divorce from his wife on the ground of her adultery with Mr. Appleton, a medical practitioner, who had attended her in her illnesses. Mr. Appleton did not appear, and the jury brought in a verdict in favour of the petitioner, with 2,000*l.* damages against Mr. Appleton, the co-respondent. Since the verdict attempts have been made to obtain a new trial on the part of the wife, and at last these efforts have been successful. The interesting part of the case, so far as it relates to medical practitioners, is, that Mr. Appleton, who is now in America, writes, through his solicitor, to state, on his oath, that he is entirely innocent of the charge made against him ; that he left England solely on account of his own private and pecuniary affairs, and without any reference to, or knowledge of, the proceedings in the Divorce Court, and that he knew nothing of the suit until he read, in America, that a verdict had been returned against him. We expressed, at the time, our incredulity of the accusations made against Mr. Appleton ; and doing little more at present than making the above allusion to the case, we may state that Mr. Appleton's version of the matter is quite consistent with all the known facts, and that his account appears to be a genuine statement of the truth as far as he is concerned.

LONDON HOSPITAL. — The foundation-stone of the new west wing of the London Hospital is to be laid by his Royal Highness the Prince of Wales on the 4th of July next.

MERCY HOSPITAL.—The following staff have been recently appointed to the Mercy Hospital, Henry street, Cork :—Senior Physician, Dr. O'Connor ; Senior Surgeon, Dr. Francis Bullen ; Junior Physicians, Dr. Cremen and Dr. O'Callaghan ; Junior Surgeons, Dr. Wycherly and Dr. O'Keeffe ; Consulting Surgeon, Dr. D. B. Bullen.

REVIEW OF THE PERIODICALS.

(Continued from page 397.)

which, it is shown, has been succeeded by a bright era in surgery; and the names of those who have ornamented this era are enumerated. Just and special tributes of praise are paid to Syme, Liston, and Lizars. The careful study of surgical anatomy is inculcated; not, indeed, "Investigations on ill-defined and obscurely-developed quantities," nor mere "transcendentalism," but observations in that "commonplace, but common sense anatomy which is of essential service to the practical surgeon." The improvement in surgical appliances and dressings, and in the treatment of wounds, calls forth a special eulogium. This improvement is shown to consist in a greater simplicity, and a more determinate effort to *follow* in the steps of Nature than was formerly adopted. The advantages gained by the more common use of stitches (in which Mr. Fergusson gives the preference to the silk thread) is pointed out, and the success of vesico-vaginal fistula, of cleft palate, and of gastrotomy, is considered to be somewhat attributable to this *simple* mode of treatment. The present method of removing stone in the bladder, namely, by lithotrity, instead of lithotomy, is likewise dwelt upon as indicative of progress in surgery. The treatment of distortions, by the subcutaneous division of those tissues which caused the malpositions, is, perhaps, the most striking example of modern improvement. In operations for cleft palate there is a vast diminution in the number of failures, and this diminution is ascribable to the division of the levator palati on each side; while the success attendant upon Taliacotian operations is declared to be more complete than was at first supposed to be possible. Allusion is made to the invention of such aids to surgical science as the stethoscope, microscope, laryngoscope, and ophthalmoscope. The achievements in conservative surgery, exhibited in resections, are not omitted; while the value which attaches to anæsthetic agents is deemed by Mr. Fergusson of such importance, as to claim for such agents a position scarcely inferior to the results of the labours of Harvey and Jenner. The lecture is brought to a close by adverting to the improvement in the means of education, and to the advantages gained by the establishment of professional societies and journals.——The Rev. S. HAUGHTON, M.D., T.C.D., communicates a paper, entitled "Notes on Animal Mechanics." This, the first article, is "On the Muscular Mechanism of the Hip-joint in Man." He gives two postulates: first, "that the amount of work done by a muscle in a given time is proportional to its weight—*i.e.*, to the number of muscular fibres in contraction;" secondly, "that the mean lengths of the different muscles employed at each joint are proportional to the perpendiculars let fall from the centre of motion of the joint upon the directions in which the muscles act." From the amount of muscle there must be a deduction made proportionate to the quantity of fascia and cellular tissue comprised in it. The corollaries are: first, "the moment of each muscle, with respect to the centre of the joint, is proportional to its weight;" secondly, "the weights of the muscles surrounding the joint may be regarded as moments of the forces, and may, therefore, be compounded by the law of composition of moments or couples." The problem to be solved is:—"Find the simplest planes passing through the centres of motion of the body on the pelvis, and of the hip on the thigh, to which the forces of the muscles of the hip-joint can be referred." There are illustrations (drawings of the os innominatum) for the purpose of explaining the author's views.——Mr. JORDAN continues his "Surgical Inquiries," the subject now considered being a simplification of the extra peritoneal operation in the varieties of strangulated hernia; with observations on the anatomy of hernia. The operation he advises in cases where the hernia is strangulated and not returnable by the taxis is characterised as "simple, slight, free from danger, and giving the power of employing the taxis with almost certainly felicitous results;" and in its nature, "an almost subcutaneous incision into the fibrous margin of the constricted aperture, the peritoneum being uninjured and even unapproached." The danger of the peritoneal operation, the facility of diagnosing gangrenous bowel, the risk incurred by exposure to the air, and by handling the bowel when inflammation of it is far advanced, are all pointed out. Some cases are adduced to show that, after many days of strangulation, genuine adhesions do not occur. One of the principal objects of his operation Mr. Jordan declares to be the avoidance of "injury to that inflammable portion of the peritoneum called sub-peritoneal fatty fascia."

'JOURNAL OF PRACTICAL MEDICINE AND SURGERY.'

Ascarides.

Some short time since, the 'Bulletin de la Société de Médecine de Besançon' published a paper by Dr. Lebon on the diagnosis of verminous and tubercular meningitis. In the course of eight years' practice at Besançon, the author states that he observed thirty-five instances of meningitis, twenty-nine of which were apparently caused by the presence of worms, and every case, save one, ended favourably; the six remaining patients were affected with granular inflammation of the cerebral envelopes, and died. Here, therefore, we have a large collection of cases which seem peremptorily to demonstrate the existence of verminous meningitis, at least at Besançon. The entire problem rests, however, in the correct interpretion of the facts observed. Although the contact of the ascarides with the intestinal mucous membrane may undoubtedly give rise to very serious morbid manifestations, all that has been said on the subject of the sympathetic disturbances, and more especially of the cerebral symptoms occasioned by the entozoa, must be received with great reserve. The cases adduced in illustration of this influence have been brought forward by perfectly trustworthy observers, and although sometimes marvellous in appearance, must be regarded as strictly true; their interpretation only is plainly open to discussion. Indeed, we may safely say that in few questions of pathology has the *post hoc* been more readily assumed to imply the *propter hoc*, and more frequently given rise to a confusion between coincidence and cause and effect.

Such is the brief summary of the two interesting introductory lectures of Mr. H. Roger's summer course at the Hospital for Infancy.

The Professor aptly quoted Voltaire's remark, that the best of all possible worlds is but a field of slaughter, in which each animated being is more or less engaged in the

amiable occupation of devouring his neighbour; and he represented the human subject as the natural prey of numberless parasites, and as an illustration of the philosophical axiom that Nature watches with careful solicitude over the preservation of the different animal genera, but takes slender account of individuals. Man, however, is capable of self-defence, and, thanks to the progress of public hygiene, will, it may reasonably be hoped, eventually triumph over some of his intimate enemies, an expectation encouraged by the gradually decreasing numbers of lumbrici and of trichini in the population of Paris, now supplied with a fair allowance of pure water, and with healthy pork-flesh.

The belief in the spontaneous development of entozoa within the human body has been discarded. The doctrine of spontaneous generation is replaced by the principle, *omne vivum ex ovo*. Davaine's microscope has revealed the existence of the ovum of several of these parasites, and it is a singular fact of natural history, that this egg, although laid in the visceral cavity, is hatched within the body, and becomes the instrument of further generation only after having been expelled from the intestine, and gathered the elements necessary to its further development. In his valuable *Traité des Entozoaires et des Maladies Vermineuses*, Mr. Davaine has shown that the ova of the trichocephalus and of the lumbricus are passed with the fæces, and are developed out of the human body, to which they return still in the egg state, but now containing an embryo, which acquires its full growth in the course of six or eight months in winter, and one month at least in summer. This embryo may live one or two years, and in that space of time easily be conveyed, by rain-water, into the rivers, rivulets, and wells which supply water for drinking or for culinary purposes. The ova may thus again reach the human digestive organs, and there acquire the degree of maturity necessary for the birth of the helminth; but in these successive migrations the ovum naturally encounters many causes of destruction. It is, moreover, a fully demonstrated fact that it is arrested by filters; hence, worms are infrequent in Paris, where filtered water is chiefly used; and although they are sometimes met with in children, the entozoa are seldom sufficiently numerous to occasion serious disease. The explanations offered by modern naturalists throw, therefore, considerable light on the obscure history of helminths, and show that the causes to which their existence has hitherto been ascribed are utterly undeserving of credit.

When the egg has thus been again deposited in the human intestine, it there meets with circumstances favourable to the growth of the worm, of which we must avow ourselves ignorant. Childhood has, in this respect, been viewed as a predisposing cause, but Mr. Roger remarks that if entozoa are more common between the ages of three and ten than at any other period of life, the circumstance is accounted for by the fact that children, more especially in the country, are liable to wander about, and drink from whatever source may be nearest at hand, without any care of the quality of the water. We may adduce, in further proof that the ingestion of impure and unfiltered water has a greater share in the production of worms than either age or hereditary transmission, the fact that nurslings exclusively fed at the breast enjoy equal immunity with the fœtus from the presence of these parasites. The same circumstance is also a powerful argument against the opinion entertained by Guersant, who, conceiving the lymphatic temperament to be favourable to their formation, and milk diet calculated to promote that peculiar condition of the system, proscribed milk diet as injurious. Mr. Roger attributes the generation of worms exclusively to the ingestion of impure water containing the ova, and therefore denies the existence of any special diathesis. The influence of age, constitution, temperament, climate, or locality, the verminous endemic or epidemic affections described by authors, and all the obsolete theories of old writers, are upset by the great fact discovered by Mr. Davaine, viz., the ova of the trichocephalus and lumbric are not developed within the human body." It is therefore obvious that the verminous epidemics described by Rhœderer and Wagner were due to the most natural causes: in the absence of beer, the patients had been obliged to drink stagnant water found in pools or in ditches bordered with excrement: the consequences are easily intelligible.

Mr. Davaine's discovery also accounts for the frequency of worms in rural districts and in certain climates. It is unnecessary to dwell on these points, which were formerly obscure but are now perfectly perspicuous.

Dr. Pangloss, said Mr. Roger, has left a numerous school. Some authors imagine that worms not only are not injurious, but are useful; that they feed on the contents of the intestines and stimulate the viscera. In the larger animals it must be acknowledged that the presence of helminths does not seem to be productive of seriously detrimental effects. Dujardin speaks of a horse who had enjoyed excellent health, and in whose body were found 519 lumbrici, 214 strongyli, and 73 tænias. This, however, would only be an illustration of the innocuousness of entoza in certain vertebrata, and in no wise demonstrates their utility; in the human subject these parasites must be viewed as unwelcome and noxious guests, which it is highly desirable to expel.

Mr. Roger did not dwell on the description of the forty-five different species of helminths which have chosen the human body for their *habitat*, but merely pointed out the principal and most common varieties, which the practitioner must necessarily be acquainted with. For the present, he confined his remarks to the history of *lumbrici*, deferring to a future occasion the consideration of *oxyuri;* but leaving aside *tape-worm* and *cysticerci*, which seldom afflict infancy, With regard to the long thread-worm, *tricocephalus dispar*—an helminth often found in considerable numbers, and supposed by some authors to have a share in the production of typhoid, on account of its being usually met with in the cæcum,—this worm never gives rise during life to any special symptoms. Its ova are very minute, and pass through filters, and the helminth is therefore met with in the bodies of persons inhabiting cities supplied with apparently perfectly pure water.

(To be continued.)

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 3.

Mr. PRESCOTT HEWETT, President, in the Chair.

Mr. TEEVAN exhibited specimens from

TWO CASES OF ANEURISM OF THE ARCH OF THE AORTA.

The first aneurismal sac was nearly as large as a child's head, and caused the death of a powerfully-built man, aged forty-four, by bursting into the right pleural cavity. It was of about six months' duration, and a blow on the sternum would seem to have been the exciting cause of its origin. The point of interest in the case was that there was an extensive varicose condition of the veins of the front of the abdomen caused by the pressure of the aneurism on the vena cava superior, thus retarding the flow of blood through the internal mammary veins. The second sac was not quite so large as the first one, and was taken from the body of a woman, aged forty-five. It was nearly filled with laminated fibrin, and by its pressure had caused absorption of part of the second right rib. Death would seem to have resulted from bronchitis, brought on by the implication of the pneumogastric nerves in the tumour.

Dr. BOWEN exhibited a specimen of

SYPHILITIC CARIES OF THE SKULL.

A man twenty-nine years of age had been eleven years in the army. He was admitted into Newport Hospital eleven months before his death on account of syphilis; whether it was primary or secondary, or whether he was treated with mercury, was unknown. After remaining there nearly five months he rejoined his regiment, but was unable to do duty. Three months later he was admitted into the Tower Hospital, London, where he died January 7, 1855. The patient was under Dr. Bowen's care during the last three

weeks of his life. He had nodes on both tibiæ, and the scars of old scrofulous glands on the neck. Three sores appeared on the head, two over the frontal region, another at the junction of the occipital and parietal. One on the forehead was deep—the bone was destroyed, and the dura mater was plainly visible; this presented a vascular appearance, but there was nothing like acute inflammation present. In the other two, though the bone was carious, it was not perforated. There was no cerebral excitement at any time; on the contrary, he was generally torpid. Pain of a continuous, but not severe, character was experienced in the head. There were old pleuritic adhesions on each side. In the right lung, in its upper lobe, there was a deposit of tubercle, hard, and about the size of a filbert. The left lung was studded with miliary tubercles, and its apex contained two abscesses, each the size of a walnut. The heart was small and flabby: the mitral and aortic valves were covered with warty excrescences. In the abdomen, the liver and omentum were attached to the anterior wall by old peritonitic bands of lymph. The liver weighed five pounds seven ounces, and was waxy in appearance. The corticle substance of the kidneys was pale. The spleen was large, and firmer than usual. The mucous membrane of the large intestines was covered with ulcers, varying in size from a split pea to a sixpenny-piece. On removing the scalp, all the bones of the skull were seen to be extensively carious; in some places the pericranium was destroyed; in others it was raised by a puriform fluid, which, being allowed to escape, showed an excavation in the skull. There were six perforations beside that one seen during life. The pericranium was firmly adherent around the openings. The dura mater was not destroyed anywhere: it was thickened and adherent around the perforations. There was considerable effusion of serum in the subarachnoid space, and each lateral ventricle contained about two drachms of fluid. The brain substance appeared healthy. Dr. Bowen remarked that the perforations and excavations followed the ordinary rule by beginning in the outer table and spreading inwards. Considerable interstitial absorption had gone on in the neighbourhood of each ulcer, especially in the immediate vicinity of each perforation. With such an aggravated form of constitutional cachexia, it is not surprising to find that there is no effort towards repair visible in the bone worth speaking of. It was probable that he was affected with primary syphilis for the first time at some period within the last eleven years. He did not know whether he had any secondary affections of the throat or skin; and as far as the history extended, he first came under treatment within the eleven months preceding his death; neither was there any history of excessive mercurialisation. If scrofula, syphilis, and mercurial cachexia had all allied themselves in this case, the rapidity with which it ran its course was not to be wondered at.

Dr. GIBB exhibited

GROWTHS FROM THE LARYNX, PARTLY REMOVED THROUGH THE MOUTH AND PARTLY THROUGH THE POMUM ADAMI.

The patient was a young lady of twenty-nine, whose voice was affected for two years, and who had obstructed breathing for two months, with hoarseness. The right wing of the thyroid was decidedly prominent and painful for five months. The laryngoscope revealed a large growth, with irregular outline, of an ashy grey colour, springing from the root of the epiglottis, extending to the right side of the larynx, involving the false cord, and covering the whole of the true vocal cord, as well as the anterior part of the left true cord. This left a small space for the passage of air posteriorly. The under surface of the vocal cords, together with their free borders, were normal, as speech was tolerably fair, although hoarse. On March 29 about one-third of the soft projecting portion of the tumour was readily removed with the laryngeal écraseur, followed by some bleeding. This produced great relief for fourteen days, when she was seized with the most urgent dyspnœa, for which tracheotomy was performed by Mr. Holthouse. Eight days later, her general health being much improved, chloroform was given, and Mr. Holthouse extended his original incision upwards, and divided the thyroid cartilage through the pomum Adami, the lateral halves being held apart by retractors. Dr. Gibb then introduced his finger upwards and removed the remainder of the growths in the larynx, partly with his finger-nail and partly with curved scissors, the tumour being soft and friable in some parts and firm in others. The latter condition extended into the right subglottis. No untoward consequences followed. Five days later she was sitting up in a chair, and on the fourteenth day she was comparatively well, eating hearty and getting stouter. Some days later the laryngoscope showed the larynx clear. Various portions examined by Dr. Andrew Clark revealed in some the transition stage of simple into malignant epithelial tissue. Dr. Gibb had no doubt of the connection between the growth in the neck and that in the larynx, and the operation he considered as most satisfactory.

Dr. MORELL MACKENZIE said that he should like to ask Dr. Gibb whether the pathological specimens submitted to Dr. Andrew Clark were those which he had removed with the wire-loop, or whether they were those which Mr. Holthouse had taken away after the larynx had been opened. He considered that it was useless to attempt to remove an excrescence, the base of which extended over half the larynx, by means of a cutting operation conducted through the mouth. Such cases could only be satisfactorily treated by means of escharotics. Chromic acid had been lately tried by Dr. Lewin, of Berlin, for this purpose. Dr. Mackenzie said that he had tried this agent, as well as nitric acid, but that he found nothing answer so well as Vienna paste. This might appear a hazardous remedy to employ, but he observed that he frequently used it with the most satisfactory results, and without a single bad consequence.

Dr. GIBB replied that the fresh portions of tumour examined by Dr. Clark were what he himself had taken away at his second operation, and although the growth was broad-based, its soft nature and lobulated form readily permitted of the removal of a portion in the wire-loop of his écraseur. All the preparations in the London museums he had carefully examined, and tabulated in his work lately published, and the majority of the tumours could have been readily removed with the écraseur without any risk, the growth in many being foliacious and disseminated, rather than broad-based. He strongly deprecated the use of Vienna paste, and pitied the unfortunate patients submitted to its use, when other and better means of relief could be applied.

Dr. MACKENZIE said that many of the specimens described in catalogues as pedunculated growths were not so in fact. In many of these so-called pedunculated growths the base was as broad as the extremity. In all the museums in London there was scarcely one growth that could have been removed with a wire-loop, except, perhaps, the specimens in King's College, which Mr. Ryland had described; but had these growths been divided they must have fallen into the windpipe, and suffocation would have ensued. Whatever might be the problematical danger of employing escharotics in the larynx, Dr. Mackenzie said that experience proved that if they were skilfully applied no evil consequences, but great benefit, resulted from their use.

Dr. GIBB likewise exhibited a specimen of

DETACHED NECROSIS OF THE CRICOID CARTILAGE

From a man aged thirty-nine, admitted into the Westminster Hospital, July 6, 1863, under Dr. Radcliffe, with acute laryngitis. Tracheotomy was performed the same night by Mr. Holthouse. In October the odour of necrosis was present; he subsequently left much improved, but was readmitted in April in a moribund state, and died the next day from extensive pneumonia. Besides old laryngeal disease, the posterior part of the cricoid cartilage was found lying quite loose and bare within the larynx.

Dr. MORELL MACKENZIE exhibited a specimen of

TUBERCULAR THICKENING OF THE INTER-ARYTÆNOID FOLD OF MUCOUS MEMBRANE.

The specimen was taken from a young lady, aged twenty-one, who had had aphonia for eight months and grea

dyspnœa for four. Tracheotomy had been skilfully performed by Mr. Mason, and the patient was in a fair way of recovery, when she took cold, and bronchitis and rapid consumption came on, and she died two months after the operation. In this case the laryngoscope had been of great value, for with it it was at once ascertained that the inter-arytænoid fold of mucous membrane was greatly thickened, and when, in addition to this, the false cords became swollen, and the laryngeal canal greatly encroached upon, the necessity of opening the windpipe was at once perceived.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

JUNE 6TH.

PUBLIC HEALTH ACT.

Mr. Augustus Smith asked for some explanation of an item of 10,600*l.* charged for contingent expenses.

Mr. F. Peel stated that this sum was required to defray the expenditure of the Privy Council Office under the Public Health Act. £3,000 was annually placed at the disposal of the Privy Council to pay medical and other officers who were from time to time deputed to conduct inquiries and experiments; 2,000*l.* was for the national vaccine establishment; 2,000*l.* for vaccination inspection, and the remaining 3,600*l.* was a matter of account arising from the medical department of the Privy Council having been unaware of the rule that payments should only be made out of the votes for the current year.

JUNE 7TH.

THE SALE OF POISONS.

Mr. H. Berkeley gave notice that on that day month he would ask leave to bring in a Bill to amend the Poisons Prohibition Act of last session.

LEGAL INTELLIGENCE.

COURT OF PROBATE AND DIVORCE, JUNE 7TH.

STONE *v.* STONE AND APPLETON.

This case, it will be remembered, was tried in the absence of the co-respondent, and a verdict found for the petitioner, with 2,000*l.* damages. A new trial was ordered on the application of the respondent. The co-respondent was in Canada, and now swore that he had never heard of the suit till about the time that it was tried, and that when he did so he started to come to England, and when he reached Boston, in America, he found that it was decided against him, with 2,000*l.* damages, and he thereupon went back. Mr. Serle now applied that Mr. Appleton might be admitted to enter an appearance to defend the suit.

Mr. Lopez opposed, denying that it was the application of the co-respondent, because the same solicitor who appeared for the wife now appeared for the co-respondent. The proceedings began in 1861, and the father and other relations of Mr. Appleton resided at the time in Devonshire; and it is not to be supposed that he was ignorant of the suit.

Adjourned to give each side an opportunity of filing further affidavits.

ABERYSTWITH COUNTY COURT, MAY 27TH.

ACTION FOR ALLEGED MALPRAXIS.

LEWIS *v.* ROWLANDS.

The plaintiff, a miner of Gellyfadoc, Llanbadarn-fawr, near Aberystwith, brought this action against the defendant, Mr. Evan Rowlands, of Goginan, the medical attendant of the mine at which the plaintiff worked, to recover 150*l.* for having, as was alleged, "improperly, unskilfully, and negligently" treated a fracture of the plaintiff's arm. It appeared that in the absence of the defendant the plaintiff was first attended by Mr. Roberts, of Aberystwith, who dressed the arm, and then resigned further care of the fracture to Mr. Rowlands, who daily attended the plaintiff. After seven days the bandages were removed. The plaintiff subsequently called in Mr. Watkins, a surgeon of Henllys, under whose attendance, for five or six weeks, the plaintiff recovered. The whole question appears to rest upon the propriety of permitting the original bandage to remain undisturbed. The defendant called Mr. William Williams, of Dolgelly, and several other surgeons, who approved the treatment adopted, and the verdict was ultimately given for the defendant.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary examinations for the Fellowship, were reported to have done so to the satisfaction of the Court of Examiners, and at a meeting of the Council on the 9th inst. were admitted Fellows of the College:—James Beddard, Edgbaston, Birmingham—date of membership, April 30, 1861; Robert Brudenell Carter, Stroud, Gloucestershire—date of membership, Dec. 12, 1851; Alfred Cresswell, P. & O. S. N. Co.'s Service—date of membership, May 28, 1858; Wm. Henry Folker, Hanley—date of membership, July 4, 1851; Arthur Wolcot Nankivell, Torquay, Devon—date of membership, Jan. 30, 1862; William Travers, Charing cross Hospital—date of membership, April 17, 1860; Bowater John Vernon, St. Bartholomew's Hospital—date of membership, April 22, 1862; William Webb, Wirksworth—date of membership, April 30, 1852; Claudius Galen Wheelhouse, East Parade, Leeds—date of membership, May 25, 1849; Henry Willey, Poplar Hospital—date of membership, Nov. 19, 1862; Henry Wotton, Gloucester place, Portman square—date of membership, Feb. 18, 1859.

At the same meeting of the Council the following members who had been elected Fellows at previous meetings were admitted as such:—Josiah Henry Selwood, Ampton place, Gray's-inn road—date of membership, Nov. 27, 1829; Charles Samuel Webber, Connaught square—date of membership, March 25, 1836.

The following Members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 8th inst.:—William Akerman, St. Just, Cornwall—date of membership, April 28, 1864; George Benson Baker, Bayswater—date of membership, April 26, 1864; Henry Todd Broughton, Bradford, Yorkshire—date of membership, May 10, 1864; William Cubitt Lucey, Bermondsey—date of membership, Jan. 26, 1864; Samuel Mills, Consumption Hospital, Brompton—date of membership, April 23, 1863; George Oliver, Bourne—date of membership, July 30, 1863; Chauncy Pusey, Surrey square, Old Kent road—date of membership, July 31, 1863; Albert Comberbach Reade, Congleton—date of membership, April 27, 1864; Frederick William Richards, Winchester—date of membership, April 26, 1864; John Henry Salter, Arundel, Sussex—date of membership, April 27, 1864; Henry Viant, Totton, near Southampton—date of membership, April 26, 1864.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the the 2nd inst.:—Edward Casey, King's College Hospital; John Foot Churchill, Poole, Dorset; George Haycock, Hackney road; Edwin Bold Pearson, Yeaveley, near Ashbourne; John Henry Salter, Arundel, Sussex; Charles Edward Squarey, University College Hospital; Henry Viant, Guy's Hospital; William John Wey, Edgecumbe street, Stonehouse; David Martin Williams, Camborne, Cornwall.

The following gentlemen also on the same day passed their first examination:—Henry Denney, Guy's Hospital; Algernon Ewen, Guy's Hospital; John S. S. Perkins, Guy's Hospital.

OXFORD.—In a congregation held on the 2nd instant, the degree of Doctor of Medicine was conferred upon Alfred Willis, St. John's College.

CAMBRIDGE EASTER TERM.—At the Second Examination for the M.B. degree, the following gentlemen were examined and approved:—Alfred Godson, M.A., Trinity College; H. W. Hoffman, M.A., Trinity College; E. T. Leighton, M.A., Caius College.

The following gentleman was examined and approved

for the degree of Master in Surgery :—Alfred Godson, M.A., Trinity College.

FATAL EXPLOSION OF GUN-COTTON.—We regret to have to announce that a serious explosion occurred last week at the gun-cotton manufactory of Messrs. Prentice and Co., Stowmarket, Suffolk, which has resulted in the death of one of the female employées, and placed in jeopardy the lives of four other persons, including the foreman of the works. The coroner's jury have been unable to determine the precise cause of the disaster, and recommend the immediate appointment of a scientific commission to inquire into all the circumstances, with a view to prevent the recurrence of similar accidents. It is known that the operation of cutting the gun-cable into short lengths of about six inches, by means of a steel blade worked by machinery, was the primary cause of danger in this instance, and it is supposed that some particles of a gritty nature accidentally coming in contact with the knife had developed sparks or a sufficient degree of heat to ignite some portion of the material, and that the flame quickly spread to the whole cable (about ten feet in length) which was at the moment lying exposed in the immediate vicinity of the cutting machine.—'Chemical News.'

VIVISECTIONS.—The question of vivisections, already discussed at the French Academy of Medicine, has now been brought before the Senate. A Mr. Grandjean, of Paris, forwarded to that assembly a petition in which he prayed that efficient measures be adopted to put an end to the abuses to which he states experiments on living animals have given rise, and he especially invited the attention of the Senate to the vivisections performed in the veterinary colleges. On the first part of the petition, the commission moved the previous question, but with regard to the second the reporter remarked that in veterinary colleges the practice complained of was carried to excess, and he conceived that the attention of the Government should be solicited to the fact. The Senate, nevertheless, rejected the petition. Although this decision is in the main favourable to the veterinary schools, and absolves them from the imputation of wanton cruelty, it has not given entire satisfaction to these institutions; and the wording of the report being of a nature to encourage further complaints from *ultra-philozoists*, the 'Journal de Médecine Vétérinaire de Lyon' alludes as follows to the subject :—"We are perfectly convinced that, in veterinary colleges, operations on living animals are not only useful, but absolutely indispensable. We willingly concede that their performance should be confined within the narrowest possible limits, but these limits can be properly pointed out only by scientific men, who needed no suggestions from the London and Paris Societies for the protection of animals. The directors and professors of the veterinary colleges whom it is at present the fashion to denounce concede to no one the exclusive monopoly of humane feelings. They use every effort to conciliate the interests of science with those of humanity, and have never tolerated the unnecessary infliction of pain on defenceless creatures, whose unavoidable sufferings they deplore, in procedures always instituted under their personal inspection." This language appears to us both moderate in its tone and reassuring for the future.—'Journal of Practical Medicine and Surgery.'

GREAT NORTHERN HOSPITAL.—The eighth anniversary dinner of this institution was held on Wednesday last at the Albion, Aldersgate street, Sir Lawrence Palk, Bart., M.P., in the chair. The Chairman having proposed "Her Most Gracious Majesty the Queen," "Their Royal Highnesses the Prince and Princess of Wales," "The Bishop and Clergy of the Diocese," responded to by the Rev. Canon Dale, and "The Army, Navy, and Volunteers," called attention to the report, of which the following is an abstract :—"The Great Northern Hospital has been established in the new premises in the Caledonian road. Donations have been received during the present year as follows :—A legacy of 300*l.* has been bequeathed to the hospital by the will of the late George Wheelhouse, Esq. It will be remembered that the hospital had its origin in a dispensary, established by the late Mr. Statham in the neighbourhood of King's-cross. Converted into an hospital, much needed by the constantly increasing northern districts, it now forms the nucleus of a great metropolitan charity. It has a large and efficient medical and surgical staff. The arrangement by which the North London Deaconesses' Institution undertook the nursing of the hospital has fully answered the expectations formed of it. Only increased funds are now wanting to make the hospital fully available for the relief of the northern districts. The receipts for the eleven months ending 31st May, 1864, amounted to 1,297*l.* 12s. 7d., the payments to 1,291*l.* 8s. 7d. The number of out-patients relieved during the same period is 44,396. To effect the most important and pressing objects, it is calculated that about 4,000*l.* will be sufficient—viz., out-patients' department, including waiting-rooms, consulting-rooms, and dispensary, about 700*l.* To render the present building thoroughly efficient, about 350*l.* To build new wards, about 2,000*l.* For purchase of the present interest in the hospital buildings, furniture of new wards, and incidental expenses, about 1,000*l.*" The Chairman then proposed, "Prosperity to the Great Northern Hospital." He pointed out that it was situated in a densely populated neighbourhood, where disease was more common than in more open districts where people had all the advantages of ventilation, and possessed a better knowledge than their poorer brethren of the means of preventing disease or stopping it on its appearance. The hospital had done much; it was pushing on to do more; and whilst he did not admit it was desirable that a hospital should be allowed to get into a state of indebtedness, still, where there was a pressure of misery, the committee were justified in stepping forward to relieve it, in the confident belief that the public would support them. The Healths of the Medical Staff, the Committee of Management, the Chairman and the Stewards, followed, and subscriptions were announced to the amount of 800*l.*

QUININE AS A PREVENTIVE OF MALARIAL DISEASE.—Dr. J. W. Page, Inspector for the United States Sanitary Commission in the Department of North Carolina and Virginia, reports that the greatest benefit to the health of the forces stationed in the malarial regions about Newbern has resulted from the regular administration of a quinine ration to the men. It is gratifying to hear this statement from Dr. Page, whose long residence in the malarial regions of North Carolina makes him a critical observer. One of the earliest efforts of the Commission, in the direction of the prevention of disease in the army, was to impress upon commanding officers and the Government the prophylactic or preventive powers of quinine. All who are familiar with the medical documents of the Commission will remember the able and exhaustive monograph by Dr. Wm. H. Van Buren on this subject. From all the columns operating in malarial regions, we have heard nothing to impair our belief in the value of quinine as a preventive of malarial disease. It should be taken in doses of three grains at bedtime, and two or three in the morning, continuously through the malarial season. Its value is enhanced when given in connection with coffee. It is scarcely necessary to state that the curative power of quinine is greatly lessened in the case of those who have become saturated with fever and ague poison, by long residence in malarial regions; of course the experience of such persons cannot be taken as impairing one's belief in the preventive power of the agent.—American Paper.

INCREASE OF INSANITY.—The 'Bristol Daily Post,' commenting on the Sixteenth Annual Report of the Somerset County Lunatic Asylum, makes the following remarks :—"The least satisfactory feature of the report, and unhappily it is one which cannot be influenced either by the committee or the medical officers, is the evidence which it affords of the increase of insanity in England. The committee state that there remains in the Asylum spare room for ten females only, and add that 'even if the Cardiff patients are removed, the annual increase is such as to make it probable that after two years there will be no spare room;' and they add, that 'at present the patients are more crowded than is desirable.' The 'urgent need for

a place for the treatment of chronics is dwelt on in the report,' and the committee state that they anticipate 'that before long they will have to apply to the Court (of quarter session) for its sanction either of a purchase or to an increase of the building.' It would be gratifying if this most unwelcome addition to the numbers of the insane could be ascribed to some exceptional or temporary cause, but, unhappily, such cannot be. Dr. Boyd, in his report to the visitors, states that 'the increase of insanity in this country has amounted to from 30 to 40 per cent.' even during the last fifteen years, and he refers to the number of new lunatic asylums that have been built in all parts of the kingdom, and to the necessary additions to the old ones. 'One of the latest asylums opened,' he observes, 'the Cumberland and Westmoreland, already requires to be enlarged, and at the Denbigh Asylum wings are to be added for 150 patients.' This is a humiliating and painful state of things, and its sadness is enhanced by the assurance that the increase is almost confined to the gentle sex. We commend it to the careful investigation of those who would be likely to consider it with advantage, as being a matter as well deserving of anxious and solemn inquiry as any that could be named."

BULLET EXTRACTED FROM THE STERNUM, IMBEDDED THERE SINCE THE BATTLE OF MALVERN HILLS, JULY 1, 1862.—Wm. O'Meagher, M.D., relates the following case in the 'American Medical Times':—Private John Kearney was wounded by a rifle bullet at the battle of Malvern Hills, July 1st, 1862, the ball entering two inches to the left of the mesial line, at the fourth rib, and lodging in the lower portion of the body of the sternum. Various efforts were made by counter-openings to remove it, but in vain; and after nine months, during which he was constantly in hospital in Washington and New York, he was discharged as unfit for service. The wound had healed to a certain extent, and he went to work at his trade of shipwright, but afterwards re-enlisted, February, 1864, when, owing to dissipation and an active campaign on Riker's Island, where he was exposed to all the deleterious influences for which that depôt gained an unenviable notoriety, and which were so well calculated to *unfit* recruits, and even veterans, for active service, the wound broke out afresh, became extensively inflamed and painful, and an intermittent attack of broncho-pneumonia was superadded. An examination with the common probes, and subsequently by Nelaton's instrument, discovered the location and nature of the foreign substance, which I at first thought was a spicula of carious bone, but finally a free incision down to the bone liberated a considerable quantity of fœtid pus, and the bullet was easily removed by a common dressing forceps. No spiculæ of carious bone were found loose in the surrounding parts, though several pieces had been previously removed while he was in general hospital. The bullet itself is irregularly flattened down to the second depression or ring at the base, with sharp and jagged edges, presenting altogether as ugly a foreign body as could well be retained with any comfort in such a position for such a considerable period. From its present appearance I should say that it must have first struck either his own or a comrade's musket, but of this he had no recollection. I think he will be entirely well in a few weeks.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JUNE 15.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, Caledonian road, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Fergusson, "On the Progress of Surgery during the Present Century."

THURSDAY, JUNE 16.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Chemical Society, 8 p.m.—Dr. Scharlemmer, "On the Identity of Methyl and Hydride of Ethyl."—Dr. Sprengel, "On Vacuum Experiments.'

FRIDAY, JUNE 17.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.; Royal College of Surgeons of England, 4 p.m.—Professor Fergusson, "On the Progress of Surgery during the Present Century."

SATURDAY, JUNE 18.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

MONDAY, JUNE 20.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JUNE 21.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

DR. CORFE is thanked for the copy of the Journal, and we have availed ourselves of the information it contains.

A VESTRYMAN.—A Licentiate of the Royal College of Physicians of Edinburgh cannot *legally* style himself a Doctor of Medicine.

RUSTICUS.—We do not advise you to neglect the study of Botany, especially as you live in the country; but it need not interfere with your other professional pursuits. A pocket-glass, a small knife, and some good manual are the only materials you will require in the study, which you should carry on practically in the fields and woods.

MR. H. J., *Manchester*.—Ozone is supposed to be only a peculiar form of oxygen, and antozone is another form. When the same body assumes different forms under different circumstances, it is said to be *allotropous*.

To the Editor of the Medical Circular.

SIR,—I beg you will allow me a small space in your valuable Journal for the insertion of the following statement:—

The 'Lancet' for 27th August, 1857, contained some interesting remarks by Mr. Weeden Cook, Surgeon to the Free Hospital, in reference to the effects produced by the external application of *manganic acid combined with potassa* in cases of cancer; and there was also inserted in the same journal, the following month, some valuable information by G. F. Girdwood, M.D., respecting the benefit derived from the application of the *permanganate of potass* in the same disease.

In 1856 an important lecture was delivered at Birmingham, at the annual meeting of the Provincial Medical and Surgical Association, by Mr. Langston Parker, Surgeon to the Queen's Hospital, "On the Treatment of Cancerous Diseases by Escharotics;" and the 'Lancet' for 22nd March, 1862, also contained a communication from W. Marsden, M.D., "On the Treatment of Epithelial Cancer by the Application of the Arsenical Mucilage." Now, as a considerable period has elapsed since the testimony of those eminent individuals was published respecting the efficacy of caustic remedies in that direful disease, I feel anxious to know the result of their more recent experience in the treatment of cancer by escharotics. I am, &c., CHIRURGUS.

Falmouth, 9th June, 1864.

DR. J. L. EARLE, *Birmingham*.—The MS. should reach London not later than Thursday evening. We are sorry to learn the cause of the delay.

DR. KIDD.—The extracts have been received, and shall be inserted as opportunity offers.

HAMPSHIRE.—There would be practical inconveniences and objections to the course alluded to, but information as to the price of a book can readily be obtained of the publisher, whose name is always given in our Reviews.

THE SOCIETY OF ARTS.—The ticket has been received.

MR. N. MCGREEVY.—The letter arrived too late for insertion this week, but shall appear in our next number.

Liquor Folii Ricini, or Fluid Extract

of the Palma Christi Plant, for increasing the Secretion of Milk in Suckling Women.

Mr. GREENISH solicits the attention of the Profession to the above preparation, which is now in great demand.

Dose: One teaspoonful three times a day.

Prepared by THOMAS GREENISH, Chemist, 20 New st., Dorset sq.

Superphosphate of Iron and

SUPERPHOSPHATE of IRON and LIME.—Particulars of these new and valuable remedial agents will be forwarded on application, by Mr. Greenish, 20 New street, Dorset square.

MINERAL WATERS IN A PORTABLE FORM.

Savory and Moore have prepared

in a GRANULAR and EFFERVESCENT Condition the Constituents of the following MINERAL SPRINGS:—

VICHY SALT—CARLSBAD SALT—PULLNA SALT—SELTZER SALT—FACHINGEN SALT—KISSENGEN SALT—MARIENBAD SALT—CHELTENHAM SALT,

&c., &c., &c.

PORTABLE AND ECONOMICAL SUBSTITUTES FOR LITHIA WATER:—

GRANULATED AND EFFERVESCING CITRATE AND CARBONATE OF LITHIA.

TONIC AND FEBRIFUGE PREPARATIONS:—

GRANULATED AND EFFERVESCING CITRATE OF IRON AND QUININE.

GRANULATED AND EFFERVESCING CITRATE OF QUININE.

GRANULAR EFFERVESCING AMMONIO-CITRATE OF IRON.

Savory and Moore beg to announce that, in

addition to the above, they are now manufacturing on a large scale all the GRANULATED MEDICINES in use, such as—

CITRATE OF MAGNESIA—CITRO-TARTRATE OF SODA—CARBONATE OF IRON, PURIFIED TAR—GREGORY'S POWDER—DR. BELLOC'S CHARCOAL, &c., &c.

AGENTS FOR MR. LIGHTFOOT'S MAGNETIC SOLUTION OF PHOSPHATE OF IRON, MR. SCHACHT'S FLUID PREPARATION OF BISMUTH.

143, NEW BOND STREET, LONDON.

King's Effervescent Citrate of Mag-

NESIA is the original Preparation for which the Proprietor received a Medal at the Great Exhibition in 1851, and has had the sanction and recommendation of the most eminent Physicians in London, and throughout the empire, for the last fifteen years, as a most agreeable and efficacious Saline aperient and Febrifuge, suitable for all ages and all climates. Sold by all Chemists. Testimonials accompany each bottle.—W. W. KING, Sole Proprietor, 15 Percy street, W.

TO THE MEDICAL PROFESSION.

Bragg's Charcoal Biscuits for

INDIGESTION, HEARTBURN, &c. &c., manufactured from the purest Vegetable Carbon. Sold only in tins, at 1s., 2s., 4s., and 8s. each, by J. L. BRAGG, Sole Manufacturer, 2 Wigmore street, Cavendish square, London. Also "IRON TONIC BISCUITS," in 2s., 4s., and 8s. Tins.

Chemists and others allowed a liberal discount.

Post office Orders made payable at the Old Cavendish-street Branch.

DINNEFORD'S

Pure Fluid Magnesia, now perfect

in purity and strength.

"Mr. Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.), specially adapted for the use of Medical Men and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

Chiming Clocks. — "The Large

clock in the centre transept is a fine piece of mechanism, one of the largest chiming." — 'Morning Post.' September 29th, 1862. Clocks by the first artists of the day for the drawing-room, dining-room, bedroom, library, hall, staircase, bracket, carriage, church turret, railways, warehouse, counting-house, musical, and astronomical. Church and turret clocks specially estimated for. Benson's Illustrated Pamphlet on clocks (free by post for two stamps), with descriptions and prices, enables those who live in any part of the world to select a clock. Also a short pamphlet on cathedral and public clocks, free for one stamp. Prize Medal and Honourable Mention in Classes 33 and 15. J. W. Benson, 33 and 34 Ludgate hill, London. Established 1749.

Watch and Clock Maker, by Special Warrant of Appointment, to H.R.H. the Prince of Wales.

Medical Transfer and Partnership.

30 BUCKLERSBURY, LONDON.

Mr. Orridge, Medical Transfer

Agent, Referee, and Valuer of Medical Property, may be consulted, as usual, at the above address.

Office Hours, 11 to 4.

MEDICAL TRANSFER AND AGENCY,

50 Lincoln's-inn fields, W.C.

Mr. J. Baxter Langley, M.R.C.S.

(King's Coll.), begs to inform the Members of the Medical Profession that he has undertaken the Medical Transfer and General Professional Agency Business till recently carried on by the late Mr. Bowmer.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to Professional business.

Gentlemen desirous of relinquishing their Professional connection, or prepared to receive partners, can be introduced to gentlemen ready to invest in bonâ-fide transferable practices and partnerships. The strictest reserve will be practised in all the preliminary arrangements, and no expense incurred (except in special cases), unless a negotiation be completed.

Gentlemen who have recently obtained their qualifications, or who may be looking for new spheres of employment as principals or assistants, are invited to communicate with Mr. Langley with a view to the satisfaction of their requirements. Having been engaged in practice himself, Mr. L believes himself peculiarly competent to give advice as to the value of partnerships or transfers. Mr. Langley can refer to the Professors of his College, Members of Parliament, Clergy, and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Competent Assistants provided without delay, free of expense to the principals. No gentlemen recommended whose antecedents have not been inquired into.

Assistants (qualified and unqualified) wishing to secure appointments are requested to communicate at once.

Office hours, from 11 till 4.—Saturdays, from 11 till 2.

Mr. Langley, 50 Lincoln's-inn fields,

W.C., has on his books at present upwards of forty genuine transferable practices for sale, requiring the investment of sums varying from 100*l.* to 2,000*l.* Several West-end Practices for immediate disposal.

Medical Assistants.—Wanted im-

mediately, competent In-door and Out-door ASSISTANTS, qualified and unqualified, for Town and Country. Apply to Mr. Langley, 50 Lincoln's-inn fields, W.C.

"Private Asylums."—A Medical

Man wishes to rent a Private Asylum, or to join one as a Resident Partner, under any advantageous circumstances. Near London preferred.—Address, confidentially, X. Y. Z., care of Messrs. TINEHAM, 57 Baker street, Portman square.

St. John's Hospital for Diseases of

the Skin, Church street, Westminster.

PHYSICIANS.—Tilbury Fox, M.D.; J. Mill Frodsham, M.D.

SURGEONS.—Erasmus Wilson, F.R.S.; J. L. Milton.

The Medical Officers attend daily at 2 p.m. Lectures on the Pathology and Treatment of Cutaneous Diseases and Clinical Lectures are delivered during the Medical Session. The Practice of this Hospital is open to all Members of the Profession and Students of Medicine.

Anatomy, Physiology, Pathology,

and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

Instruments made of the Laminaria

DIGITATA, Uterine Tents, see 'Med. Times and Gazette,' Nov. 28th, 1863, page 558, T. G. Wilson, on Uterine Tents. Couper's dilating Uretha Bougies and Styles for dilating the Lachrymal duct, as used in the Royal Ophthalmic Hospital, Moorfields, may be had of C. W. KROHNE, 241 Whitechapel road, London.

Weiss's Illustrated Catalogue, con-

taining nearly 800 Engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price 5s.

62 Strand, London.

"This Catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced; and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour, which we are glad to see strictly observed in this Catalogue."—Vide 'The Lancet,' Sept 12th, 1863.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

BY J. LUMLEY EARLE, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 376.)

The Remedies.

The Use of the Catheter.—When summoned to attend a labour, the medical attendant should never omit to take a female catheter with him. It may be required to be used during labour to relieve the pain and discomfort consequent on a distended bladder, or to facilitate instrumental aid, or to prevent the occurrence of post-partum hæmorrhage. After delivery, in some cases of flooding, the introduction of the catheter may stop the loss at once, or most materially assist the action of other remedies. The instrument which I am in the habit of using is a silver female catheter, flattened on the upper and lower surface. A flattened catheter is passed much more easily along the female urethra than a round one. When a woman is flooding, the best way to pass the catheter is to feel for the meatus with the finger, and not by finding it with the eye. Blood is constantly draining from the vagina, and the mucous membrane is covered with it, so that it is not at all easy to find the meatus by looking for it; on separating the labia, blood immediately wells up continuously, and effectually obscures the orifice we are seeking. Of course, one unaccustomed to pass the catheter in the female will find either way difficult, but the surgeon who can pass the catheter without exposure will, in cases of flooding, prefer finding the meatus by the touch, simply because it is more easy. There are two or three ways of passing the catheter without exposure. The following is about as good as any: Pass the first finger of the left hand, in front of the patient, between the legs, and place it between the labiæ on the smooth vestibulum. Then glide the finger slowly backwards until the smoothness of the vestibulum ceases, and we come upon a rugged portion of mucous membrane. At the very junction of the smooth and rough, the orifice of the meatus will, by a little manipulation, be detected, in primiparæ, small and firm, in multiparæ generally large and patulous. The tip of the finger must be kept on the orifice, to act as a guide to the catheter, passed from behind by the right hand. No force is required in the introduction of the catheter into the bladder; if it should not pass easily, we may be sure either that it is not in the meatus at all, or that the tip of the instrument is hitched in the mucous membrane of the orifice, or, more rarely, further up in the meatus. It should be taken out, and re-introduced.

The Administration of Astringents by the Mouth.—In those cases where the flow of blood occurs rapidly and in large quantity, astringents taken by the mouth are of no use. They do not act quickly enough. Hæmostatic medicines are only useful in cases where the loss takes place in the form of free draining, and continues for several days. The mixture I usually prescribe contains one drachm of gallic acid, a drachm and a half of dilute sulphuric acid, and forty minims of Battley's solution of opium in six ounces of compound infusion of roses: two table-spoonfuls to be taken every three or four hours. Many medical men do not believe in the efficacy of astringent medicines given in hæmorrhages connected with parturition. In flooding after delivery I have the greatest faith in them, if their administration be confined to the cases which occur in the form of excessive and long-continued draining. As they do not interfere with the application of local remedies, and as they cannot do harm, there is no reason why we should not administer them in the hope of their acting beneficially.

Compression of the Abdominal Aorta.—Up to the present day, compression of the aorta has only been used in cases where all other remedies have been tried in vain; and it has become absolutely necessary, in order to give the patient a shadow of a chance, to adopt some means which will stop the loss, until the uterus can be roused to due contraction. It may be effected either through the abdominal walls, or by the hand within the cavity of the uterus. Except in stout women, the aorta can generally be easily compressed through the walls of the abdomen, on account of their great laxity after delivery. If the compression has to be kept up for any length of time, it will be less irksome to the medical attendant, and more agreeable to the patient, to effect it through the abdominal walls than by the hand in the uterine cavity. Compression of the aorta has, without doubt, saved the lives of some women, and deserves a more general trial than it has hitherto obtained. It acts beneficially in two ways: it prevents a further loss of blood, while we are exciting the uterus to contract through the agency of other means; and it lessens the depression by retaining the blood in the most vital parts of the body —viz., the brain, heart, and lungs. In some cases, where the aorta could be easily reached, we might, probably with great advantage, employ compression at a very early stage of the treatment. To show its practical value, I subjoin the notes of three cases. The first occurred in the practice of Mr. Blount, and is related in Mr. Ingleby's work 'On Uterine Hæmorrhage:"—"On the termination of labour, Mrs. W. was, to all appearance, quite comfortable. In about half an hour she complained of being very faint; her countenance was very pale and anxious. There had been little or no external hæmorrhage; and, on placing my hand over the abdomen, I could not distinguish anything resembling the uterus. By friction and compression some discharge was forced away, but no beneficial effect resulted; the hand was, therefore, passed into the uterus, and a mass of coagula which distended its cavity cleared away. By this means, and by gently irritating its inner surface, contraction was promptly effected. Though the discharge had now considerably abated, the exhaustion was very great, the pulse being exceedingly feeble and frequent, and the patient appeared sinking. I now placed my hand on the abdomen just above the uterus, and, from the spareness of habit, easily distinguished the pulsation of the aorta, and made pressure so as to intercept its current of blood. This was continued with increasing advantage for half an hour, and, as the patient was much revived, I then withdrew my hand. Upon the withdrawal of the hand, the sinking immediately returned, attended with giddiness in the head and a slight return of the hæmorrhage. Pressure was again made for the space of two hours with the same good effects. Twice during this period I allowed the blood to pass the lower extremities, but with the same unfavourable results as before. A modified and less effective pressure was continued for four hours longer, before it could be entirely dispensed with." The second case occurred also in the practice of Mr. Blount. Mr. Ingleby, who was present, says:—"Whilst pressure was exerted over the aorta, the uterine contractions were provoked by two fingers passed through the os uteri. Whenever the pressure over the vessel was withdrawn, there was an almost instantaneous return of hæmorrhage and syncope, and some hours elapsed before the patient's safety was secured." The third case came under the observation of Mr. James D. Brown, of Haverfordwest, and is published in the 'Medical Gazette' of December 2, 1842:—"I (Mr. Brown) attended a woman, æt. thirty-four, in her fourth confinement; she was a person of lax fibre. The labour was natural, and terminated in six hours; but a violent fit of shivering seized her before the expulsion of the child. I was prepared for the event; and, as I expected, flooding came on to a fearful extent. The placenta was loose, and came away with the first gush. The uterus again dilated, but I passed my fingers into its cavity, in order to excite it to contract, and at the same time made pressure externally, but hæmorrhage still continued in spite of every effort—pressure, cold applica-

tions, &c., &c. She had fainted and recovered, and was suffering from the effects of the loss of blood. I decided on trying the effects of pressure on the abdominal aorta. I had no difficulty in finding it. I made a firm pressure on it, which gave the patient some pain. The hæmorrhage ceased directly, and did not recur: I had it in command; to feel satisfied of that, I gently relaxed my grasp once or twice, when bleeding again commenced. I still kept up pressure on the uterus, and administered secale cornutum in brandy and hot water. The woman rallied, the uterus contracted firmly and permanently, and I let loose the vessel after pressing it for nearly two hours, and all went on as well as possible." Mr. Brown states that a similar case occurred to him about two months after, in which he adopted the same means, and with the same satisfactory results.

Plugging the Vagina.—In flooding after delivery, plugging of the vagina should be *very rarely* resorted to. The uterus after labour is so extensible, that to plug the vagina, in the majority of instances, would be merely to convert an external into an internal hæmorrhage. It is only applicable in those cases in which the uterus is contracted, and, yet notwithstanding, there is an excessive draining of blood. We must guard against internal hæmorrhage by external pressure; and if there should be evidence of flooding going on in the cavity of the uterus, the plug must be immediately extracted. For plugging the vagina after delivery, there is nothing equal to an india-rubber air pessary, as it is easily introduced, most effectually prevents the escape of blood, and is easily removed.

Opium.—In some cases of flooding, this drug is of great value. I quite agree with Dr. Ramsbotham, that it is not advisable to administer it when the hæmorrhage is due to inertia of the uterus. The most agreeable preparation of opium is Battley's solution, and it may be given in a large dose—thirty minims, at least.

Brandy.—It acts beneficially in two ways: it rallies the patient and, in some cases, sets up contraction of the uterus. One of the first things we should see to, on our arrival at the house of a patient in labour, is that there is a supply of brandy. Many a woman has lost her life from a want of this precaution. When brandy is wanted in the middle of the night, it is often most difficult to get it. Public-house keepers are prohibited from selling it after twelve p.m., except, I believe, in cases of illness, and they generally will not listen to that plea, unless you are backed up by the authority of a policeman, which individual is proverbially difficult to be found when he is wanted. It should be the best *pale* brandy, or we may find a difficulty in getting the patient to drink but a very small quantity of it, especially if she is unaccustomed to spirits. It may be given freely, diluted with half the quantity of cold water, or pure, according to the amount of depression. The chief object for which it is given is to rally the patient; but it undoubtedly, in some cases, also assists in arresting the hæmorrhage, by bringing on contraction of the uterus. In two or three cases of lingering labour from inertia, I have brought them to a speedy termination by a glass of hot brandy-and-water.

HOSPITAL REPORTS.

KING'S COLLEGE.

CASE I.—STRANGULATED HERNIA. UNDER THE CARE OF MR. HENRY SMITH.

M. B., æt. sixty, married, and mother of six children, was admitted February 13, 1864, suffering from symptoms of strangulated hernia of the left side. By occupation she is a needlewoman, and, for now a period extending over thirty years, she has noticed a swelling in the left groin, as well as one in the right, which is much smaller. These disappear at times, but return. The bowels were not opened since the 9th of this month, and since they have been confined she has observed the swelling in the left groin to have grown larger and harder; she has also had a shivering. Sickness came on during the evening of the 9th, and continued up to the time of her admission. Suffering from these symptoms, she came into the house on the day above-named, and on examination a strangulated femoral hernia was ascertained to exist. She was removed into the operating theatre, and when under the influence of chloroform, Mr. Smith operated by making one straight vertical incision through the integuments, and then, dividing the subcutaneous structures, got down upon the sac, which was the size and shape of a small plum. The sac was opened and a few drachms of serous fluid escaped. The bowel was found to be very tightly constricted, and very much congested; a bistoury was then passed in, and Gimbernaut's ligament being divided, the bowel was returned. A bandage was then applied, and she was removed to bed. A pill of gr. i. of opium was administered immediately on her being put to bed.

Feb. 16th.—She has done well since the operation, but the bowels have not been opened. Early this morning she had an enema of thin gruel, and two grains of calomel were put on the tongue. Since this the bowels have been twice moved.

Feb. 17th.—The wound in the abdomen does no look very healthy. A poultice is to be applied. The bowels have not been opened again.

Feb. 19th.—Bowels again opened, but not till after the exhibition of castor-oil. There is a good deal of pus about the wound, and so she is desired to continue the poultice.

March 7th.—She is discharged. Cured.

CASE II.—STRICTURE OF THE RECTUM.

M. B., æt. thirty-three, married, was admitted on Feb. 17, 1864.

History.—For the last eight years she has been troubled with a stricture of the rectum, which, however, does not seem to get worse. The fæces that have been passed now for some time are in diameter about half an inch. She states that she has been gradually getting weaker. There is no syphilitic history. The only cause which she assigns is, that, about eight years since, she had some affection of the right knee-joint, for which she was admitted into St. Bartholomew's Hospital, and that as the knee got well the stricture came on. The knee is now quite free from all trace of disease. There is a good deal of pain experienced in the passage of her motions. No cancerous history can be found to exist in her family. There is also a fistula of the left side.

Feb. 20th.—The patient being under the influence of chloroform, Mr. Smith divided the fistula and stricture at the same time, and in his usual method; oiled lint was then placed in the wound, and she was removed to bed.

March 7th.—No bad symptom has arisen since the operation, and she is to-day discharged, very much relieved.

CASE III.—STRICTURE OF URETHRA.

T. W., æt. sixty-eight, a labourer; admitted Nov. 5th, 1863.

History.—He has usually enjoyed good health, until seventeen years ago, when he contracted gonorrhœa, and within a year after his contracting this disease he found a difficulty in passing water; this gradually increased, until about eighteen months since, when it became so bad, that he was obliged to apply for relief to the Westminster Dispensary, where catheters were passed at different times. The size of the last instrument passed was No. 6. Feeling thus very much relieved, and trusting to the effects of medicine, he discontinued attending the Dispensary, and the stricture got worse; he then applied as out-patient at King's College, his application bearing date Oct. 26th. He was seen by Mr. Smith, and a small catheter was passed. As, however, the stricture was very tight, Mr. Smith ordered him into the hospital, and he was admitted on the day above-named. The water now dribbles slowly away, and there is no continuous stream. On the day of his admission, being in great pain, he was ordered

Ammon. sesquicarb. ʒij.;
Acid. citric, ʒij.;
Tinct. hyoscyami, ʒiss.;
Aquæ, ʒviij.—ʒj. quartâ quâque horâ.

Nov. 9th.—The urine is very albuminous, and he is evidently gradually sinking.

Nov. 11th.—On the morning of this day he died, after being five days unconscious.

The post-mortem appearances were as follow: There was a good deal of pus found in the pelvis; an abscess of about the size of a walnut was found in the left lobe of the prostate gland, and pointed towards the rectum. A stricture of the urethra was situated in the anterior part of the bulb; there was also a pouch extending from the bladder forwards under the left crus penis. The right ureter was dilated, and contained pus; the right kidney was very much wasted, and the cortical portion was very nearly destroyed. The left kidney contained some fatty deposits; the bladder was very much dilated, its walls immensely hypertrophied, and its cavity containing pus.

CASE IV.—INDURATED PATELLARY BURSA.

E. W., æt. eighteen, a shopwoman, admitted on Nov. 5th, is a delicate subject.

She states that she has not been in the habit of kneeling much, but for six months the right patellary bursa has grown hard and swollen. It has been painted with iodine. There is, over the patella, a firm tumour as large as a pigeon's egg, but there is no inflammatory action about it.

Nov. 6th.—Mr. Smith removed a cyst about the size of a small walnut; it contained blood: another and a smaller cyst, which he also removed, contained sero-sanguinolent fluid. The wound was closed by three sutures, and the limb was placed on a straight splint.

Nov. 20th.—Discharged. Cured.

CASE V.—STRICTURE OF THE RECTUM. UNDER THE CARE OF MR. WOOD.

F. B., unmarried; admitted into the female surgical ward as a patient, from stricture of the rectum. She is rather stout and plethoric; has had good health until lately. There is no history of syphilis. For twelve years she has had difficulty in passing her motions, and has suffered much pain. Has been under treatment at several hospitals, but obtained little relief. For about four years she has been in the habit of passing a bougie herself, and has generally succeeded in passing it up for a distance of about five inches; for the last fortnight, however, she has been unable to pass it at all. Bowels have been opened a little every day. There is a good deal of inflammation of the right buttock. Date of admission, July 28th, 1863.

CASE VI.—DOUBLE PSOAS ABSCESS, ACCOMPANIED WITH CURVATURE OF THE SPINE AND VERTEBRAL DISEASE.

F. McB., æt. eight, admitted under Mr. Wood, Sept. 2nd, 1863, suffering from several abscesses in different situations. Lives at 33 Carey street; has always had plenty to eat and drink; he has one brother, who is quite healthy. Had whooping cough three years since, and after it got intermittent fever; he subsequently became a patient from some affection of the right hip, for which he was leeched and blistered; he never suffered any pain in the hip, but had a very severe pain in the right knee, and for a long time he could not walk without limping. He has never suffered any pain in the back nor in the situation of the abscesses, which were detected two months ago, when he was being washed, and when they had attained a size sufficient to make them cognisable. The abscess at the upper and back part of the thigh was poulticed. There is apparently a large pelvic abscess pointing just above Poupart's ligament of the left side; there is also another abscess at the back and middle part of the right thigh, which, having been opened, gave out a large quantity of pus. There is angular curvature of the lumbar regions, some of the lower dorsal vertebræ being implicated in the disease. He does not complain of pain when the vertebral spinous processes are struck, nor has he ever had pain in the back, pain being confined to the right knee.

Sept. 5th.—He is covered with an eruption like that of scarlatina, and is feverish; tongue is coated and red at the sides, not having the appearances usually met with in scarlatina; there is no sore-throat; the abscess keeps discharging; it is poulticed; the skin is hot and the pulse is 125.

On Sept. 3rd he had been ordered and had begun to take

Acid. sulph. dil., ℥vi.;
Spts. ether. chloric, ℥xi.;
Liq. cinchonæ, ℥xx.;
Aquæ, ℥j. ms. ft.; haustus ter in die sumend.

On Sept. 5th he was ordered

Liq. ammon. acet., ʒss.;
Spts. ether chloric, ℥v.;
Mist. tragacanth, ʒj. ms. ft., haustus ter in die sumend.

Sept. 6th.—Sunday; in the morning he did not look so well, and was sick in the course of the day, but no immediate danger was feared; a few minutes before twelve o'clock p.m., he took some brandy, and was speaking to the nurse; at twelve p.m., however, he died quite unexpectedly.

Sept. 7th.—Post-mortem and post-mortem appearances:—The body was thin; a large psoas abscess was found on the left side, pointing above Poupart's ligament, and had also extended under it; there was also a psoas abscess on the right side. The abscess at the back part of the right thigh does not lead to the spine; the hip-joint was anchylosed, and there was extensive disease of the bodies of the lumbar vertebræ, and the anterior part of the spine in this region was covered with a tuberculous deposit; there was also deposit of tubercle in the kidneys; the liver seemed healthy; the heart was healthy; there were very fine clots of fibrin in its interior; the brain seemed perfectly healthy.

CASE VII.—UMBILICAL HERNIA IN ADULT MALE.

J. B. æt. thirty-nine, admitted on Nov. 24th, 1863, into the Albert Ward.

History.—Is an assistant to a boiler-maker; is married; states that two years ago, when laid up with rheumatic fever, he noticed that he had a small swelling, about the size of a hazel-nut, above the navel, and that it felt quite soft. He has been employed at very hard work for the last eight or nine months, and the swelling has in consequence increased in size; when he ceases from his work the swelling gets smaller, but does not disappear altogether, and when reduced it comes back again. He has never worn a truss for it. It sometimes causes him dragging pains at the stomach, which are increased as he is walking; he also suffers a heavy pain after his food, palpitation of the heart, and shortness of breath. Does not suffer from winter cough, but he had a cough on his admission, which, however, has, after the lapse of a few days, become much better. He does not look to be a strong man, and is very nervous. He has one little child, a girl; she is free from any appearance of rupture, nor, to his knowledge, has any of his family suffered from such a complaint. The bowels are quite regular. There is an oblong tumour with its long axis from side to side; it is about the size of a large walnut, soft, reducible, dilating forcibly when he coughs; it seems to communicate with the abdomen by an irregular opening. He has never worn a truss; the bowel has never been strangulated.

Ordered

Acid. nit. dil. et
Acid. mur. dil. āā ℥x;
Spts. ether chloric, ℥x;
Decocti taraxaci, ʒj. ms. ft.; haustus ter indie sumend.

Mr. Wood thinks that as the man suffers from palpitation of the heart and from difficulty in breathing, it is better not to submit him to an operation; the patient has therefore had a truss made to keep the hernia from protruding, and was discharged.

CASE VIII.—INGUINAL HERNIA OF THE LEFT SIDE.

C. F., æt. nineteen months, admitted Sept. 30th, 1863, into the long female surgical ward, for the treatment of an inguinal hernia of the left side.

History.—Is a healthy but passionate child. The rupture came on when he was six months old, after a violent fit of screaming, occasioned by a pin sticking into him. When it first appeared, it was about the size of a small apple; then it was not particularly noticed for some weeks. None of the same family are ruptured. The rupture is on the left side, is of the size of a large pear, and not unlike that fruit

in shape, being very large for a child of the same years as the present patient ; so large is it, that it cannot be properly kept up with a truss. The hernia has been originally oblique, but in consequence of its size it has drawn the rings opposite to each other, and in this way stimulates a direct hernia. The rupture is readily reduced, but hard to keep up. The testicle can be seen and felt at the bottom of the scrotum. The child is in very good health, but the rupture seems to make him fretful.

Oct. 8th.—The mother not conforming to the rules of the hospital, the patient was discharged.

Feb. 13th, 1864.—Re-admitted Feb. 13, 1864, under the care of Mr. Wood.

The hernia is very large ; the testicle also has become enlarged.

Feb. 13th.—Mr. Wood performed his usual operation for the radical cure of this affection in children, using for the purpose the rectangular pins : the child's buttocks were fastened to a pillow to keep them well raised.

Feb. 20th.—The pins were removed. There has not been any unfavourable symptoms, and there is a good deal of consolidation in the course of the inguinal canal. Some tapeworms have been passed.

He is discharged, cured.

REVIEW OF BOOKS.

The Croonian Lectures for 1864, *delivered before the President and Fellows of the Royal College of Physicians of England : The Significance of Dropsy as a Symptom in Renal, Cardiac, and Pulmonary Diseases.* By W. R. Basham, M.D., Fellow of the College, Senior Physician to the Westminster Hospital. Pp. 86. London : Churchill and Sons. 1864.

It is now a long time since dropsy was considered to be a substantive disease and to depend upon a want of symmetrical action between the absorbent and the (imaginary) exhalant vessels. It has now subsided to the rank of a symptom, the cause of which is to be sought in structural, though often insidious, changes in important vital organs, and the treatment of which is to be guided by the light of modern pathology. The subject of dropsy, therefore, is not an inappropriate one to introduce as the material for the Croonian Lectures at the College of Physicians, seeing that the more correct notions as to the pathological changes which induce dropsy are among the triumphs of modern medicine, and that our improved knowledge is mainly due to the happy discovery made by an English physician, Dr. Bright, as to the changes effected in the kidney under certain conditions of disease. Since the period when Bright's disease was first made known as a new pathological fact, the industry and the ingenuity of the medical world have not only investigated all the minute changes in the kidney which accompany or originate this affection, but they have proved that it belongs to a family of allied degenerative changes which produce analogous lesions in many organs and textures of the body. Of the three lectures of which Dr. Basham's series consists, two are devoted mainly to the consideration of renal dropsy and the pathological conditions of the kidney and the urine ; and the third treats of cardiac and pulmonary dropsy. The opinions expressed are characterised by extensive knowledge, both theoretical and practical, and the course of treatment recommended is in accordance with the cautious but enlightened doctrines of the present day. The lectures are illustrated by six very good plates, exhibiting the general character of the degeneration of tissues in Morbus Brightii, the character of the sputa in various pulmonary disorders, and the changes which take place in the morbid deposits in the heart and arteries in various forms of cardiac and pulmonary disease.

A CHILD died at Dartford the other day from eating buttercups.

THERE are at the present time 30,000 blind men and women in Great Britain and Ireland, and nearly all of them are poor.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Professor FERGUSSON continues his course of lectures "On the Progress of Anatomy and Surgery ;" and as the lecture is also reported in the 'Medical Times and Gazette,' we give an abstract of it elsewhere.——Dr. CHARLES MURCHISON commences some "Contributions to the Etiology, Pathology, and Treatment of Scarlet Fever." This disease appears to have become more fatal during the present century than in former periods, and "there are some grounds for believing," says Dr. Murchison, "that as small-pox has diminished under the influence of vaccination, scarlet-fever has continued to increase." The latter appears to be particularly prevalent in Great Britain, although it prevails over the whole of the continents of Europe and America. In Asia and Africa it is very rare, and in India it is said never to be met with, although a closely allied affection is observed from time to time. Some statistics are quoted by Dr. Murchison to show that childhood and infancy are the periods most liable to the attacks of scarlet-fever ; but even old age is not exempt, for fatal cases have occurred in persons above eighty-five years.——Mr. BERKELEY HILL relates "Two Cases of Syphilis showing a prolonged Incubation Period, and Communication of the Disease by Secondary Contagion." The first case was that of a man who presented some coppery patches near the right eye and the cheek, and who, it was found, had received a blow on that part while fighting, and had had the part *sucked* by his antagonist. The latter was also examined by Mr. Hill at the hospital, and was found to have a sore at the corner of his mouth, and some indurated scars on the penis, evidently of a syphilitic character. Both the patients improved under the use of mild doses of mercury, and the second patient took, also, iodide of potassium.——Dr. C. W. BINGLEY relates a "Case of Poisoning by Arsenic," the poison being discovered after death, but the mode of its administration during life being unknown.

THE 'MEDICAL TIMES AND GAZETTE.'

The original lectures "On the Progress of Surgery during the Present Century," delivered by Professor FERGUSSON at the College of Surgeons, are continued, the second of the series being now published. The object held in view in the present lecture by Professor Fergusson is "to refer to a subject on which he has been long and deeply interested." The experienced surgeon, with a full reliance on the powers of Nature, at one time waits upon, at another time guides her, either gently or with rude force ; or again, when occasion requires, exerts his skill in coercing her, since it is his mission to struggle with her, she being in error. The objects of men of inquiry, when they leave the beaten paths, may be "to produce positive novelty ; to get proof that a certain practice is so good, that it should be more largely followed out, or so bad that it should be abandoned." The modern treatment of aneurism by compression is cited as a striking instance of the progress of surgical science, and the tribute of praise which it has earned is awarded to the Irish

school. Progress is sure to be opposed: the arrest of hæmorrhage by means of the ligature had to contend with opposition till the operation was established beyond all doubt to be invaluable; while, in our own day, the plan introduced by Simpson of checking bleeding by acupressure has not yet ceased to struggle with opposition. When Hunter tied the femoral artery for popliteal aneurism, he was had in derision by those occupying high places. The progress of surgery is exhibited in no surgical proceeding more forcibly than it is in the resection of joints in those cases where "the joint is irremediably affected, or placed beyond the hope of cure within a reasonable time." Parke, Monro, Jeffray, Crampton, had all practised and brought forward the practice of conservative surgery, to which Professor Fergusson made reference; but it was reserved for Syme to educe proofs so convincing of its practicability and utility, as to gain for it a place in surgical science. It is a great error to suppose that bare bone cannot become re-covered, and that a limb is hopelessly useless when its principal joint communicates with every motion a sensation of grating. The maintenance of this error has caused the loss of many fingers and thumbs, and even of many of the larger limbs. Conservative surgery—a term introduced by Professor Fergusson—is not shown more plainly in the treatment of any surgical affection than it is in that now pursued for the removal of constant pain in the tibia, dependent upon the presence of pus deep in the bone. In former times amputation would be resorted to; but the simple practice of trephining the bone, so as to allow the escape of the pent-up matter, answering every purpose, is found to be sufficient for cure. Thorough appreciation of a well-performed amputation is by no means incompatible with a still higher appreciation of a procedure which would render needless any such amputation. The term Conservative Surgery is new, but the line of treatment comprehended in that phrase must not be considered synchronous. The tying of the femoral artery for aneurism in the ham was a great feat in conservatism, yet at the time of its adoption this peculiar nomenclature was unknown. Other examples of conservatism are to be found in the treatment adopted for the tissues surrounding a diseased joint—in the treatment of simple tumours, which are prominent on the surface—of diseased testicle, where excision is requisite—of "skin, merely stretched and attenuated over disease." The disadvantage connected with removal of *seemingly* redundant integument is well illustrated in a remarkable case of Mr. Liston's. In the patient alluded to redundant skin had been taken away at the operation, but afterwards there was a contraction of the remainder of the integument, that caused a "gap extending from near the angle of the mouth up the cheek to the temporal region and to the side of the nose, which exposed the tongue and lower part of the mouth." Conservatism is exhibited in the treatment of caries, necrosis, tumours of the maxilla, or at the inferior extremity of the tibia or femur; as also "in cunning operations on the fingers, the hands, or the feet, for their preservation;" in excision of the clavicle, instead of sweeping off the entire extremity; in removal of the whole of the scapula, or in the taking away of only certain diseased parts; and in the excision of the heads of bones, the shafts being allowed to remain.——Dr. JAMES DANNET communicates "Two Cases of Fracture of the Skull," of which one is submitted to notice in the present number of the Journal. The patient, a lad aged sixteen, fell from a height of about thirty feet, sustaining a deeply depressed fracture of the skull; trephining was practised, and the sunken bone raised on a level with the sound. The case is interesting because of the perfect restoration of the faculties subsequent to the operation. Elevation of the depressed bone was followed by contraction of the right forearm, probably from reflex irritation of the base of the brain.——Mr. REDFERN DAVIES contributes an article entitled "Cure of Inguinal Hernia in Children." The object he seeks to obtain is the excitation of inflammation sufficient to cause an effusion of lymph or plasma to such an extent as to block up the inguinal canal, and to get union of the walls of this channel. "For my own part," he says, "I put an almost unbounded faith in the curative powers, in children's ruptures, of a properly fitting truss, continually worn, and regard an operation only as an adjunct to treatment by pressure, rendering it more certain and speedy. The simplicity and freedom from danger of the operation constitute a strong recommendation for its adoption."

THE 'BRITISH MEDICAL JOURNAL.'

Mr. BERNARD E. BRODHURST continues his lectures "On Orthopædic Surgery," his present subject being talipes, or club-foot. The non-congenital talipes varus is described as depending mainly on paralysis, but sometimes on spasm; but equino-varus is a much more common form of distortion. The treatment of equino-varus is described as consisting of two stages—the object of the first being to reduce the distortion to equinus, and secondly to remove the condition of equinus. The first part of the treatment, therefore, consists in the section of the tibialis posticus and tibialis anticus tendons, and the second in dividing the tendo Achillis. Mechanical treatment is also necessary, and an apparatus, constructed by Mr. Bigg, to be worn on the foot, is described as very efficacious.

THE 'GLASGOW MEDICAL JOURNAL.' No. XLV. April, 1864.

Dr. T. MCCALL ANDERSON contributes some "Cases illustrative of Diseases of the Ear," his present paper containing a short sketch of the principal forms of obstruction of the Eustachian tubes, including a description of Politzer's new method of treatment. This treatment consists of the introduction of a catheter, open at the end, which is placed in the nose, and having at the other end an india-rubber bottle. The patient is then told to take a mouthful of water, and the tube is introduced into one nostril, and the india-rubber bottle is suddenly compressed, while the patient swallows the water. By this means the soft palate is made to separate the cavity of the nose from the mouth and throat, and the air from the india-rubber bottle is driven into the Eustachian tubes.——The second article is devoted to the Townley case, which is discussed at some

length; the opinions of the writer being adverse to the supposition of Townley's insanity.——Mr. J. THOMSON gives a "Statistical Report of Five Thousand Cases of Obstetricy" which have occurred in his own private practice. His cases seem, generally, to have been attended with success, the exception being in puerperal fever, more than half of the cases having terminated in death. The forceps were applied in 104 cases, with only two deaths; and Mr. Thomson states that he has never had occasion to apply the long forceps, or seen a case where their use seemed to be desirable. He therefore thinks that they might be omited from the list of obstetrical instruments.——Dr. JOHN GRAY coutributes a paper "On the Gastric Juice," giving a sketch of the composition and action of that fluid.——Dr. W. WHITELAW, of Kirkintilloch, gives an amusing dissertation "On Extra-Academical Medical Education," advocating the inculcation of sound scientific principles as an antidote to the fanciful theories and erroneous practices of the present day.——Dr. H. MACCORMAC, of Belfast, contributes "Fifty Aphorisms in respect of Tissue Metamorphosis, as illustrating the Production of Tubercle." His leading principle is, that tubercle is caused by the retention of carbon in the system, and that the elimination of the carbon is, therefore, the best cure for tuberculosis.——Dr. A. B. BUCHANAN relates a case of "Malignant Fibro-Cellular Tumour involving the Ileum;" and MR. EDWARDS offers some "Notes on Cases of Injury to the Skull and its Contents," the cases being four in number, three being fracture of the skull, and one abscess in the cerebellum.

THE 'JOURNAL OF MENTAL SCIENCE.' April, 1864.

The present number of this Journal contains "Some Stray Notes on Foreign Asylums," by Dr. W. CARMICHAEL MCINTOSH, who describes a few of these institutions in Savoy and Switzerland. Dr. Guggenbühl's Institution for Cretins at the Abendberg is represented as being almost deserted since the death of its founder; and its efficacy in the cure of cretinism is doubted by the author of the paper. ——Dr. JOHN HITCHMAN relates the particulars of "An Interview with George Victor Townley, with Reflections thereon," the conclusion drawn being that the convict was not insane.——The Rev. W. G. DAVIES contributes a paper "On Memory and the Brain," the object being to show the connexion of this faculty both with the cerebral organisation and with the other faculties of the mind.——Dr. H. G. STEWART contributes a very elaborate paper "On Hereditary Insanity," founded upon and illustrated by a great mass of statistical evidence.——BARON MUNDY, M.D., in "An Oasis in the Desert of Non-Restraint," gives an analysis of Dr. Ludwig Meyer's paper on the non-restraint system, Dr. Meyer having visited this country and seen the good effects of the English treatment of insanity, and having written an article on the subject in the 'Allgemeine Zeitschrift für Psychiatrie.'—— The clinical cases comprise "A Case of Primary Cancerous Tumour of the Brain," with remarks, by Dr. G. MACKENZIE BACON, and the particulars of "A Case of Sudden Death at Hayward's Heath Asylum," by Dr. C. L. ROBERTSON. The latter patient had been treated by the wet sheet and the tincture of digitalis, but after death it was discovered that a large vessel had been ruptured in the brain, and this result was in no way attributable to the treatment pursued. The rest of the number is filled up with reviews of British and foreign works relating to psychological medicine.

'JOURNAL OF PRACTICAL MEDICINE AND SURGERY.'

(Continued from page 401.)

Let us now turn to the history of lumbrici, a class which has been assumed by writers on the subject as the prototype of entozoa.

We have alluded to their mode of generation and propagation. Mr Roger neither agrees with the optimists, who consider them useful, nor with the pessimists, who ascribe to them the most serious consequences, but assumes an intermediate position. In his opinion the alleged dangers are a question of number, and few children have not two or three lumbrici wandering without injury in the intestinal cavities. In one instance a child passed in the course of five months as many as two thousand five hundred lumbrici without apparent detriment to his health. It may, however, be stated as a general fact, that the symptoms indicative of their presence are proportionate in gravity to their numbers. Ten or twelve of these entozoa, for instance, give rise to few, if any, morbid manifestations. Diminution of appetite and some slight diarrhœa of a mucous character may be observed, forming an aggregate of symptoms of slender import, far different from the formidable descriptions to be found in classical treatises. The dotted aspect of the tongue, foul breath, capricious appetite, peculiar cast of countenance, the dilatation of the pupils, dull colour of the skin, dry cough, and lactescent urine, are all, in Mr. Roger's opinion, purely chimerical. These signs may coincide with the presence of tape-worm, but never with that of lumbrici, however numerous. The latter can only occasion the symptoms of enteritis, from mechanical irritation, which may, if very intense, impart to the case the aspect of typhoid.

Bretonneau has asserted that, in subjects who during life have suffered from verminous diseases, the gastric mucous membrane is usually found in a softened and disorganised condition. This appears improbable, from the well-known fact that lumbrici habitually dwell in the small intestine, from which they seldom ascend towards the stomach. They more usually follow the course of the bowels, and seldom give rise to the agglomerations viewed by Wedekind as a cause of obstruction and vomiting of fæcal matter. These formidable symptoms have, however, been observed by Messrs. Guersant and Charcelay in two children, who recovered after having passed, the first thirty-seven, and the second sixty lumbric worms. We may not unreasonably admit that, under the influence of slight intussusception, the accumulation of a dozen or fifteen lumbrici in one spot may induce symptoms of obstruction; but Mr. Roger is less inclined to grant implicit belief to the sympathetic disturbances alleged to be due to the existence of these entozoa. It is on this point especially that authors have indulged in flights of fancy, and have mistaken coincidences for cause and effect. Cerebral symptoms, for instance, were contended with by the exhibitions of calomel, which is an excellent parasiticide; worms were passed, and the cure was ascribed to their removal. If convulsions, consequent on indigestion, supervene during the evolution of the teeth, an aperient is prescribed; the child passes worms, and the helminths are represented as having occasioned the convulsions. Mania, hysteria, eclampsy, catalepsy, tetanus, chorea, epilepsy, palsy, hydrophobia not referable to rabies, amaurosis, and even deaf muteness, have all been attributed to the presence of helminths. Some of these functional symptoms may doubtless have supervened in persons afflicted with tænia, but we are treating at present merely of lumbrics; and Mr. Roger distinctly asserts that he has never observed even convulsions, the most frequent of all the sympathetic affections above enumerated, which could

fairly be accounted for by the existence of these worms. We must, in addition, remark that it is very difficult positively to ascertain the amount of influence exercised by the entozoa, because, on the one hand, the diseases alluded to are sometimes obviously unconnected with any such cause, and because, on the other, children often pass a large number of worms, although they have never suffered from convulsive, eclamptic, epileptic, or choreic fits of any description whatever.

With regard to verminous (so-called) meningitis, its existence might be admitted at a period when, the study of morbid anatomy being more neglected than at present, meningeal granulations were passed over unheeded, and the symptoms occasioned by their presence were referred to a few inoffensive lumbrici found in the small intestine. The cases in which a cure was effected after the expulsion of worms must be viewed as instances of mere coincidence. Dr. Mangin has placed on record the history of several children, between the ages of three and nine years, who were all affected with convulsions and passed a large number of entozoa. Three recovered and two died, the latter being affected with acute hydrocephalus. "It is obvious," observe Messrs. Rilliet and Barthez, "that in these subjects the cerebral symptoms were entirely unconnected with the presence of the lumbrici."

In conclusion, Mr. Roger absolves the entozoa from the production of the sympathetic symptoms which have been laid to their charge. He does not, however, acquit them of the accusation of causing mechanical irritation. We have alluded to their evil effects in the intestinal tube; we now turn to the consideration of the mischief induced by their migrations from one organ to another.

They sometimes, for instance, wander into the stomach, and may give rise to pain and nausea, and occasionally induce emesis, during which the helminth is rejected. In the œsophagus, the lumbric causes a sensation analogous to that produced by the presence of a foreign body ascending towards the pharynx, and the patient complains of a distressing titillation in the duct. A lumbric may possibly enter the cystic duct, but only in adults in whom the biliary passages have been enlarged by the previous escape of a gall stone; it is at least doubtful if such an occurrence is possible in children. We should not omit to state that entozoa, on reaching the pharynx, may penetrate into the nasal fossæ, the Eustachian tube (Winslow), and subsequently work their way out through the auditory duct (Bruneau), or pass into the larynx and trachea, giving rise to fatal suffocation unless the worm is promptly expelled in a fit of coughing—a fact observed by Mr. Davaine in one of the fourteen cases collected by Mr. Arronssohn and himself. Mr. Davaine remarks that, by the process of elimination, the practitioner is soon led to suspect the presence of a lumbric—a suspicion promptly converted into a certainty if, by direct inspection with the finger or eye, the worm is found partially extruding from the glottis, a circumstance which has been noted in almost 50 per cent. of the patients.

In another class of cases the helminth passes into organs which are not its customary habitat, subsequently to a morbid process in which the parasite has had no share. Thus, ulceration of the stomach or intestine, or vesico-vaginal fistula, may explain the admission of worms into the peritoneum or bladder. The lumbric, however, is not the agent of the perforation. The spiculæ of the helminth are not sufficiently powerful to break through a texture not previously softened by disease. Mondière contended that the worm might work its way by merely parting, without dividing the fibres, and adduced in proof of this view the presence of worms in abscesses; but these puriform collections are not the result of the passage of the entozoa, but of causes foreign to the existence of the helminths; and when the latter reach the cavity, adhesions have already formed which diminish the gravity of the disease, and are even conducive to its ultimate cure.

The diagnosis cannot, at the present day, be allowed to repose on the fantastic semeiology to be found in classical works. The itching of the nose is a mere popular indication without value. The practitioner should never assert the presence of worms, unless they have been seen, or unless the ova have been recognised with the microscope in the fæces—a mode of investigation which Mr. Davaine has shown to be possible. When, however, parents suspect that their children are affected with worms, it would be injudicious utterly to deny their existence. In doubtful cases it can do no harm to prescribe a proper vermifuge, and this is a safer practice than to incur the risk of learning that an unsuitable one has been exhibited immediately after the physician's departure.

The treatment thould address itself to a twofold indication, viz., the expulsion of the worms, and the prevention of their reappearance.

In the first place, Mr. Roger rejects all anthelmintics which act mechanically, such as zinc grains or iron filings, alluded to by Bremser. The most reliable medicines are Gigartinia helminthocorton, semen-contra, wormwood, and soot for the poor, and santonine for subjects in easy circumstances.

The *Corsican moss*, or *Gigartinia*, may be prescribed in powder in doses of gr. xv.—xxx., in preserves or baked apples. A filtered infusion of ʒj.—iv. of the moss in eight ounces of milk is a most effective remedy, of not unpleasant taste.

Bremser recommends the coarse powder of *Semen-contra*, recently bruised, in ten or fifteen grain doses, or an infusion of two or three drachms in milk or beef-tea.

Wormwood (Artemisia absinthium) may be given in the shape of an infusion of ʒj.—iv. in four ounces of water or milk.

A mixture of two drachms of *soot* with an equal amount of coffee, infused in four ounces of boiling water, sweetened and strained, forms a not very tempting, but a cheap and efficient beverage.

A paste of *pumpkin seeds*, prepared with one or two ounces of seeds boiled, bruised in a mortar and mixed with honey, has also been recently recommended.

Santonine, a more expensive remedy, may be exhibited in the shape of sweetmeats or drops, flavoured with chocolate; each drop or *dragée* contains one grain of the remedial agent; one, two, three, or four grains of santonine may be given. Mr. Roger seldom exceeds this quantity.

The Professor also alluded to Mr. Cruveilhier's vermifuge syrup, which he and Messrs. Rilliet and Barthez have always found beneficial. It contains one drachm of each of the following substances—viz.: Senna leaves, rhubarb, semen-contra, southern-wood, Corsican moss, tansy, and artemisia; these drugs are infused in eight oz. of water, and a sufficient quantity of sugar is added to form a syrup, a table-spoonful of which is taken for three successive mornings.

Mr. Cruveilhier states that this syrup has sometimes caused the expulsion of as many as sixty lumbrici in one day. Messrs. Rilliet and Barthez prefer this preparation to Bremser's electuary, which is efficient it is true, but so intolerably disagreeable to the taste that children often cannot be induced to take it.

Whatever vermifuge may have been selected, some aperient—calomel or castor-oil, for instance—should subsequently be prescribed. It is then judicious to administer a spoonful of bark wine every evening for a week, in accordance with a precept laid down by Mr. Cruveilhier.

This method of treatment generally relieves the child for a time, but it is further necessary to prevent the reproduction of the worms; and strict rules of hygiene, especially as regards the water used as a beverage, must then be attended to. In this point lies the whole gist of the preventive treatment, and the attention of local administrations cannot be too earnestly invited to the important practical facts on which Mr. Davaine's researches have thrown unexpected light.

PRIZE ESSAY ON ANÆSTHETICS.—The Mississippi Valley Association offers a gold medal of the value of one hundred dollars for the best essay on anæsthetics and their use. It is open to the world for competition.—'Amer. Med. Times.'

THE MEDICAL CIRCULAR.

WEDNESDAY, JUNE 22, 1864.

THE ARCHBISHOP OF YORK ON MEDICAL EDUCATION.

On the occasion of the late distribution of Prizes and Certificates of Honour at the St. Mary's Hospital Medical School, the Archbishop of York, who presided, offered some remarks upon the subject of Medical education, which are deserving of notice as coming from a prelate who is possessed of undoubtedly high talents, and who has had, moreover, very great experience in the work of education from his long connexion with the University of Oxford. Nevertheless, many of his remarks are inapplicable to the subject of Medical education, in consequence of the wide difference which exists between the training necessary for our Profession, as compared with the system with which the Archbishop is most cognisant; and indeed it is almost impossible to draw a comparison between them, as the elements of the two cases are so exceedingly dissimilar.

The species of education with which the Archbishop of York is most familiar is no doubt that which has long been pursued at our two principal English Universities, especially that of Oxford, in which he has held several high official appointments. The leading studies at these great seats of learning, until very lately, have been the classics, mathematics, logic, and a little divinity; and although very energetic efforts are now being made to introduce modern sciences and modern languages into the curriculum of education, classics, mathematics, and logic still hold the most prominent position. The chief part of the student's period of residence at either University is spent in reading or attending lectures or demonstrations (given by the College tutors) on classics, mathematics, or logic; and, as is perfectly well known, hundreds and thousands of Cambridge and Oxford graduates have studied and learned little else at their alma mater, and their special professional information, if they have acquired or needed any, they have picked up somewhere else. Now we do not in the least undervalue this kind of knowledge; on the contrary, we highly prize it, and we readily admit that the training of the English Universities is one of the best ever devised to develop a youth into a scholar and a gentleman. We even hope that the members of our Profession will avail themselves more and more of the opportunities now opening to them, for pursuing their Medical studies at Oxford and Cambridge, the authorities of which are daily offering new facilities for the acquisition of natural, including Medical science, on the part of students.

All we assert is, that the Archbishop, in offering his observations on the course of Medical education in the London schools, is hardly a competent adviser, inasmuch as he knows but little either of the system pursued or of the persons who direct or follow it. We must state at once that the Archbishop, with graceful and becoming modesty, admits his incompetence in this respect; and in commenting upon his remarks we do so with the utmost regard for the general good sense which they contain, and for the soundness of the views on which they are based.

We have, on former occasions, disposed of the absurd complaint as to the enormous number of lectures supposed to be enjoined upon, or attended by, the modern Medical alumnus, and we have, therefore, not much sympathy with the students who are stated to have cheered most vehemently when the Archbishop pleaded for mercy to be shown them on account of the labours of this kind which are imposed upon them. We do not personally know the system pursued at the St. Mary's Hospital Medical School, because we have neither studied there nor held any appointment within its walls; but, at the risk of being reproved for ignorance, we may assert that the plan does not materially differ from that pursued at other Hospital Medical Schools, and that the students do not attend more lectures than are enjoined upon them. If they do so, then they act of their own free choice, and have, of course, no ground of complaint. Now, supposing that the students of this institution are intending to become Doctors of Medicine of the University of London, or Members or Licentiates of the College of Physicians, or Members of the College of Surgeons, or Licentiates of the Society of Apothecaries, we really do not observe, on perusing the published Regulations of any of those bodies, that there is such an herculean weight of lectures heaped upon them that they have any just ground of remonstrance. The University of London requires them during four years to attend some five courses of lectures, the subjects to be chosen by themselves; the College of Physicians, spreading its curriculum over three or four years, indicates the subjects to be studied, but not the number of lectures to be delivered; the College of Surgeons, with rather more precision, requires the students to attend lectures on anatomy and physiology, the former four times a week, and the latter *twice* a week (no very grievous task), during two winter sessions, and also lectures (number not specified) on surgery and other subjects; the Society of Apothecaries requires the students to attend lectures and hospital practice, but specifies no number of lectures. In fact, nearly the whole of the subjects are practical, as anatomy, chemistry, materia medica, botany (which are all purely practical subjects in their very nature and essence); and in order that there may be no mistake as to the practical character of the other pursuits, the printed Regulations enjoin *Practical* Chemistry, Dissections and Demonstrations, Clinical Medical *Practice*, *Practical* Midwifery and Vaccination, &c. In a note on one of the subjects it is added, for the further information of those who may be obtuse in their perceptions:—"By practical chemistry is intended a specific course of instruction in the laboratory, with an opportunity of *personal manipulation* in the ordinary processes of chemistry

and of acquiring a knowledge of the various re-agents for poisons."

Now, any persons in their senses who read the foregoing Recommendations of the Metropolitan Medical Licensing Boards, must surely see that if any of the Medical Schools overburden their students with lectures, and neglect to afford them the means of practical instruction, they are acting in opposition to, and not in conformity with, the Regulations with which they are bound to comply; and as a necessary consequence of this corollary, it follows that if the students allow their minds to be so overweighted they have only themselves to blame. The worthy and learned Archbishop evidently seems to think that the modern teaching of chemistry and anatomy consists in the delivery of long-winded and dry dissertations on such matters as the opinions of Hippocrates, Galen, Celsus, Boerhaave, Stahl, Paracelsus, Van Helmont, and so forth, while the real work is done by the student himself. "I take it," says the Archbishop, who, however, admits that he knows little of chemistry, "that in the case of chemistry, you cannot leave all your test-tubes and retorts simmering and fizzing, go off to lectures, and return, without a certain interruption and loss of time and material, and without a certain fret and worry of one's thoughts. I presume the same is the case with regard to dissection," &c.

Now, these are most unfortunate illustrations on the part of the Archbishop, for the fact is that practical anatomy and chemistry cannot be pursued by the student in his own room, and that he must, and ought to pursue them under the guidance of competent teachers, who instruct him in the proper use of test-tubes and retorts, and in the proper way of dissecting; and his duty at home is to note down what he has heard and seen in the laboratory or the dissecting-room, or to read in manuals or other books provided for him the explanation of the phenomena or the dissections he has witnessed. So in medicine and surgery, he is indeed (and we think very properly) required to attend some lectures in order to obtain an idea of arrangement of the subjects of study, but he is also required to attend at the bedside of the patient, to listen to the clinical observations of the physicians and surgeons, to witness or to assist at the post-mortem examinations and the demonstrations of morbid anatomy, and to handle the different instruments used for the detection or the treatment of injuries and disease.

To allege, then, that the student is obstructed in his progress by the number of lectures he is compelled to attend, or that he deserves any pity on this account, is perfect nonsense. He is required, it is true, to study a great number of subjects, but they are mostly practical, and he is enjoined, at least by the English Corporations, to study them *practically*. When candidates are remanded to their studies by the examining bodies, it is chiefly from the want of this practical knowledge, which the hospital authorities are called upon to provide, and we believe do provide, and of which the student is bound to avail himself.

SUMMARY OF THE WEEK.

CONVERSAZIONE AT THE COLLEGE OF PHYSICIANS.

On Saturday evening the President and Fellows of the College of Physicians of London held their annual *conversazione*, which was very numerously attended, the attraction being increased by the anticipated visit of royalty. With the praiseworthy punctuality so characteristic of the present royal family, the Prince of Wales arrived exactly at nine o'clock, the hour fixed for the commencement of the proceedings, and many of the visitors who came in late did not obtain a sight of him at all. He was looking remarkably well, and took a lively and intelligent interest in the objects of art and science presented to his notice. He was accompanied by Prince Louis of Hesse, and was conducted through the rooms by the President of the College, Dr. Watson. Besides the fellows and members of the College, there was a large gathering of the Surgical Profession; and among other notabilities we observed Lord Wensleydale, Lord Chelmsford, Lord Belper, the Lords Justices Turner and Knight Bruce, and many others. Among the curiosities of the evening was the veteran William Lawrence, who was looking very well, and who, we are informed, entered the College arm in arm with a bishop, whose title we could not catch, but we were assured it was not Bishop Colenso. The exhibition of articles of scientific and artistic interest was copious and attracted great attention, an array of microscopes forming, as usual at such meetings, a prominent part of the display. Messrs. Powell and Lealand exhibited the beautiful phenomenon of the circulation of the sap in the cells of the Vallisneria spiralis with 1-25 object-glass, and living specimens of the Volvox globator, a creature standing on the confines of the animal and vegetable worlds, but now referred to the latter; and the circulation of the blood in the branchia of the newt. Mr. Ladd, besides the exhibition of microscopes, showed his interesting experiments on the vibration of sonorous bodies, the waves of sound being shown by means of lenses to assume definite and visible forms. Mr. Jabez Hogg exhibited, under the microscope, specimens of the Trichina spiralis, the entozoon lately described as having committed great ravages in Germany, and Dr. Thudichum presented the same parasite in several stages of its development. Mr. Ross exhibited his binocular microscopes, showing minute objects both achromatically and by polarised light; and Dr. Lionel Beale displayed his microscopic preparations of the liver, kidney, and medulla oblongata, and the healthy and inflamed circulation in the web of the frog's foot. Among the literary curiosities was the first book printed in England by Caxton: this precious relic is the property of the College, and is in excellent preservation, the type being clear and legible and the pages bearing no appearance of its great antiquity. It should be mentioned that the refreshment department of the *conversazione* was served with great liberality, enormous and tasteful bouquets of flowers and a cornucopia of choice fruit crowning the tables. The latter gift of Pomona was not merely intended for exhibition, but was distributed

among the guests of the evening. The company, which numbered somewhere about six hundred, did not separate until a late hour, and the proceedings afforded universal satisfaction.

THE NAVAL MEDICAL SERVICE.

It would appear that "in the lowest depths there is a deeper still," for a writer in the 'Medical Times and Gazette,' who signs himself R. N., thus contrasts the position of a Medical Officer in the Army and Navy respectively :—

POSITION AND PROSPECTS OF A MEDICAL OFFICER.

In the Army.	*In the Navy.*
Roomy quarters, and all the comforts of a life on shore uninterrupted.	A hammock in the cockpit and no cabin; or, at the best, a dark, unventilated room, six feet by four, with innumerable annoyances.
Duty done, he is free to walk out where and when he pleases, unrestrained by any cause whatever.	Unable to move without a boat, which may be, and is often, refused, and which, if not refused, is pretty certain to be ill-appointed and unfit for the accommodation of officers.
Commodious hospital and an efficient staff, completely apart from the barracks, and free from all petty annoyances.	Insufficient accommodation for the treatment of the sick, and unavoidably exposed to the chances of a thousand-and-one petty annoyances at the hands of the executive.
Continued service on full pay, and, therefore, ability to serve the allotted period without a break.	Frequent compulsory loss of time on half-pay, thus protracting the period of service indefinitely.
Considerable increase of pay on foreign service and in the field, with an equitable share of prize money according to relative rank.	No increase of pay on foreign service or otherwise, and a marked distinction to their prejudice in the distribution of prize money relatively with other officers.
The rank of Surgeon-Major acknowledged in the 'Gazette,' and promotion to the higher grades tolerably certain, and pretty free from the taint of favouritism from any quarter.	No acknowledgment by 'Gazette' or separate list of the rank of Staff Surgeon, and promotion to the higher grades to be obtained almost exclusively by the sacrifice of independence necessary to secure the favour of some powerful naval influence.

THE GRIEVANCES OF THE ARMY MEDICAL OFFICERS.

An important meeting of the Metropolitan Counties Branch of the British Medical Association was held on Monday, the 13th inst., in Soho square, on the subject of the grievances endured by the medical officers of the army, and a series of speeches were made, and resolutions passed (an abstract of which we have given elsewhere) in favour of redress. We are glad that this meeting has been held, and we hope that the example will be followed by other local associations throughout the empire; for it is only by such means that the complaints of the Army medical officers can be heard and their wrongs represented to persons in authority. It now clearly appears that great dissatisfaction prevails throughout the service, and that the officials at the Horse Guards are endeavouring to stifle the voice of complaint and remonstrance. It has been broadly asserted in some quarters that the chief fault lies at the door of the Director-General of the Medical Department, who is betraying the interests of his profession while keeping himself in favour with his military superiors; but we have been informed, on authority which we cannot discredit, that such is not really the case. We are led to understand that Dr. Gibson is in no way responsible for the breaches of faith on the part of the Horse Guards towards the medical branch of the service, of which the latter so loudly complain, and that, on the contrary, he is strenuously exerting himself (although, unfortunately, in vain) to procure justice for his professional brethren. We are told on the same authority, however, that the Horse Guards are pursuing a most offensive course towards the whole of the medical service, the chiefs of that service included, and that the Commander-in-Chief is surrounded by advisers who, in the matter to which we allude, are exercising a very prejudicial effect on his mind. On this and other grounds, we rejoice that the voice of the Profession in general is making itself heard, and we learn that no time will be lost in seeking interviews with the Secretary of State for War, to represent to him the present state of the Army Medical Service, and to make him acquainted with the real facts bearing upon the important questions connected with that division of the army.

THE POOR-LAW MEDICAL SERVICE.

The following extract from a report of a Select Committee of the House of Commons, published last week in the newspapers, represents, we fear, the whole of the concessions which are likely to be made to the Poor-law Medical Officers :—

"There are no sufficient grounds for materially interfering with the present system of medical relief, which was made the subject of special and lengthened inquiries by select committees of this House in the years 1844 and 1854. The recommendations of those committees were for the most part carried out by the orders of the Poor-law Board, and the system of medical relief appears to be administered with general advantage. Your Committee, however, recommend that in future cod-liver oil, quinine, and other expensive medicines, shall be provided at the expense of the guardians, subject to the orders and regulations of the Poor-law Board."

This is truly a munificent concession, for which our medical brethren will, no doubt, be duly grateful, and which the Poor-law Guardians will probably interpret into a pretext for reducing the present miserable salaries doled out to the medical officers. In the same report, also, an apparent boon is conferred upon the medical officers by placing the power of dismissal of officers solely in the hands of the Poor-law Board; but the value of this arrangement will be apparent to everyone who knows the manner in which the Board always takes the part of the local guardians. Still, it is true that *something* has been gained; and we agree with some of our contemporaries, that more might have been achieved, if the Profession had been true to one another. Very great merit is due to our indefatigable friend, Mr. Griffin, for the unwearied zeal he has evinced in fighting an up-hill battle on behalf of his Poor-law medical brethren; and we are glad to learn that a testimonial is to be presented to him, in acknowledgment of his devotion and his self-sacrifice in the cause. We shall

be glad to promote the objects of Mr. Griffin's friends by every means in our power.

GENERAL CORRESPONDENCE.

THE USE OF MERCURY.

To the Editor of the Medical Circular.

SIR,—As you have been kind enough to allow me space, in one of your former numbers, to make a few remarks upon a paper that was read before the Harveian Society, some time ago, by Dr. Charles Drysdale, entitled "Evidence against the Internal Usè of Mercury in Syphilis and other Diseases," I hope you will be good enough to permit me, once more, to make a few further remarks upon a letter which appears in the MEDICAL CIRCULAR of the 25th of May last, from the same gentleman, speaking on the same subject. I may beg to remark, in the first place, that Dr. Drysdale seems to me to forego or modify now, in a great measure, some of his former untenable arguments respecting the internal use of mercury in syphilis and other diseases, when he does condescend so far, even, as to attach any weight or importance whatever to the opinions of your London Physicians respecting the nature and action of mercury in syphilis and other diseases. "I believe," says Dr. Drysdale (in his last letter), "that I am only speaking the general opinion of London Physicians at the present moment, when I state that mercurials are considered as quite contra-indicated in all states of the constitution coming under the category of scrofulous, whether hip-joint or other disease." So it is well to see that Dr. Drysdale has, at last, come to terms with the London Physicians upon even one very important point at least—viz., the great danger of using mercury in scrofulous diseases. "And it appears to me," says Dr. Drysdale, "to be a most ill-judged practice to ingest a most destructive drug for weeks or months into the system, in order to try experiments on the solution of an indurated mass, such, for instance, as the solvent powers of the bichloride of mercury on the induration of the cervix uteri." So I do not believe that many of the London Physicians will be inclined to dispute this point either with the learned gentleman, Dr. Drysdale. And when the body of the Profession shall consent to treat syphilis in the manner recommended by Mr. Syme, "I, for one," says Dr. Drysdale, "shall have nothing further to say." Then, again, he says: "My attacks are levelled against those who treat syphilis by the ingestion, for several months, of a daily dose of this most dangerous drug." Now, surely Dr. Drysdale must forget himself here, as we all know that his attacks were levelled against the internal use of mercury under any shape or form whatsoever. "But with the mild mercurial school it is difficult to come to terms," says Dr. Drysdale, "as they do not assert anything categorically, but merely state, in general terms, that mercury does good in syphilis; to which all I can reply is, that I do not think it ever does any good; but I also do not think that a few mercurial pills, given for a week or so, are worth speaking about either for or against." Now, surely Dr. Drysdale ought to have known, before making such a rash assertion, that a few mercurial pills, being given regularly every night and morning, for only one week or so, would be quite sufficient to effect and salivate most persons, and might, therefore, act as a perfect antidote to the venereal virus. But well may Dr. Drysdale begin to tell us that we do not assert anything categorically, but merely state in general terms that mercury does good in syphilis, while he himself can bring nothing forward to prove his arguments, unless we take for granted that a certain Dr. Fricke, a German doctor, did really cure 15,000 cases of syphilis, in the Hamburg Hospital, without ever having used a single grain of mercury, which shows clearly, and makes him (Dr. Drysdale) believe, that Fricke has completely put to rout the believers in the absolute necessity of treating syphilis with mercury. Now, how Dr. Drysdale has been led to believe all this, or to put such implicit faith in the mere statements of foreigners, is really more than I can comprehend. So Dr. Drysdale sums up and concludes, at last, by thanking Drs. Griffith and Sisson for their determination to discover flaws in his evidence as to the injurious effects of the internal use of mercury in all diseases, and by bestowing also upon these two most worthy gentlemen a very high eulogium, both for their single-mindedness and candour as compared with the rest of the Profession, either in London or elsewhere. But why Dr. Drysdale has thought fit to extol, in such unmeasured terms, the great merits of these two, at the expense of all the rest of the Profession, is more than I can conceive. So, as I have trespassed too far already on your valuable time and space, Sir, I must not trouble you at present by bringing forward a number of cases—both of syphilis and other diseases—which I do know and have seen to be cured by the skilful and judicious use of mercury, after many other kinds of medicines had been tried on the same, but to no use or advantage whatever.

Then all that I need now say on the subject is, that I think mercury will stand its ground always as a most useful therapeutic agent, notwithstanding the violent and one-sided attacks that Dr. C. Drysdale has levelled against it; and this has been told to him more than once already, even in presence of the Harveian Society, both by Mr. Ernest Hart and Dr. Graily Hewitt; and although the latter gentleman, Dr. Graily Hewitt, does not consider mercury to be a proper remedy in acute hydrocephalus or puerperal peritonitis, still he thought it a most useful remedy in syphilis and other diseases: so it is scarcely fair, then (to say the best of it), for Dr. Drysdale to fly off to all parts of the globe in search of evidence to prove against poor little Hermes, once the most obedient and winged messenger of the gods—and a most upright and straightforward little gentleman he is always found to be. Go where you will, or find him where you may, you shall find him to act and conduct himself always in the same most decided and uniform manner, and always anxious to be seated on the neat, clean little shelves of the apothecary, clothed in his lovely little jacket of the red, white, and blue. But why, then, does Dr. Drysdale go and fly round all the world in search of evidence to bear witness against poor little Hermes?—"Mutant cœlum, non animum, qui trans mare currunt." And so it is, and always will be, with Mercury, who will stand his ground, I have not the least doubt, against all the attacks that have been levelled against him, and the cruel ordeal to which he has been subjected of late through the instrumentality of Dr. C. Drysdale.

I am, &c.,
N. MCGREEVY.

Lurgan, June 11, 1864.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—JUNE 13.

VACCINATION.

Sir J. Pakington asked the Vice-President of the Committee of Council on Education whether, in accordance with the statement of the Lord President last year, "that the Government were considering the best means of effecting an improvement in the Vaccination Law," and having regard to the great loss of life from small-pox which had lately occurred in London, it was the intention of her Majesty's Government to introduce any measure on that subject in the present session.

Mr. Bruce said there could be no doubt that a very large and unnecessary loss of life resulted from neglect of the provisions of the Vaccination Act. The right hon. gentleman was aware that, although obligatory, the successful application of the Act depended on the active concurrence of boards of guardians, vaccinating surgeons, and parents of the children. A similar question having been put this year to his noble friend the President of the Council, he stated that in his opinion there were only two methods by which the disease could successfully be grappled with. One was by increasing the compulsory powers of the Act, the other by offering pecuniary inducements to the vaccinating surgeons. Parliament, the noble lord thought, would not sanction greater compulsory powers, and he did not see his way to the application of the other alternative. He understood that notice had been given in the other House

of an intention to introduce a Bill on the subject which would be referred to a Select Committee. He hoped that measure would have the effect of strengthening the law and removing the evil now complained of.

LUNACY (SCOTLAND) BILL.

The Lord Advocate obtained leave to bring in a Bill to continue the deputy commissioners of Lunacy in Scotland, and to make further provisions for the salaries of the deputy-commissioners, secretary, and clerk of the General Board of Lunacy. The Bill was subsequently brought in and read a first time.

THE GRIEVANCES OF THE ARMY MEDICAL OFFICERS.

SPECIAL GENERAL MEETING OF THE METROPOLITAN COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

A special general meeting was held at 37 Soho square, on Monday, June 13th, at 4 p.m.; Francis Sibson, M.D., President, in the chair. The object of the meeting was "to consider the present position of the Army Medical Department, and to take such steps in the matter as might seem advisable."

The President, in opening the proceedings, remarked that the meeting had been called to consider a subject of the greatest importance. The state of the medical service of the army had become such, that for about two hundred vacancies, there were but few or no candidates; and the authorities, in this state of things, had applied an extemporaneous remedy, by appointing acting assistant-surgeons for home duty. It must be plain that, when a service of such high position as the medical department of the army was not supplied, there must be some fault at the bottom. The army medical officers were placed in a disadvantageous position, in being disabled from standing on their own defence; and, therefore, they had a special claim to such protection and advocacy as could be afforded them by this Branch, and by their professional brethren in all parts of the kingdom. He would remind the meeting, that the British Medical Association had had a great share in obtaining for the naval medical officers the Warrant of 1859; the provisions of which, he believed, were still carried out. He called on Dr. Stewart to move the first resolution.

Dr. Stewart supposed that the members were well aware of the dissatisfaction which existed among the medical officers of the army, arising out of the circumstance that the distinction between combatant and non-combatant officers was kept up resolutely, and very injuriously to the position of the medical men and interests of the soldier. The disastrous results of the conflict between the military department and the medical had been shown in the Crimean war, where the military authorities had positively refused to give effect to the recommendations of the medical officers. In the Peninsular war, the recommendations made by Sir James McGrigor to the Duke of Wellington were carried out; for, if there was any hesitation, Sir James used to remark that he had advised what he thought right, and that the responsibility of carrying it out or neglecting it lay with the Duke. But now the position of the medical department of the army was such, that the lowest step had been reached; at least, it was by many hoped that matters had become so bad, that the intervention of the medical profession could not but be successful. After the Crimean war, a commission had inquired into the state of the medical department of the army; and the result of their labours was the granting of the Warrant of 1858. This warrant placed matters on such a footing, that universal satisfaction prevailed both among medical men in the army and in civil practice. It was thought that there would be no recurrence to the former unsatisfactory state of matters; but the warrant had been obtained in spite of the army authorities; and these, by a series of partial regulations, had retracted that which was most valuable in it. Dr. Stewart dwelt, *inter alia*, upon the alterations made in Clause xvii. of the warrant; and observed that he thought enough had been said to make it by no means wonderful that there should be a deficiency of candidates. As to the employment of civilians to perform the duties of military medical officers, this was thought bad enough during the Crimean war; but what could be said, when the army medical staff was not sufficient even in the time of peace, and recourse was had to an expedient which should be regarded only as an extreme war-measure? The true reason why men entering the medical profession would not look to the army as a career, was a want of confidence in the good faith of the army authorities. The Warrant of 1858 had been so often altered, and so extensively abrogated, that medical men were unwilling to place themselves in a position in which they could be subjected to indignity. It was a remarkable fact that, while the army authorities had raised the standard of medical education for the army, they had diminished the inducements to enter the service; so that, as was lately shown by Dr. Parkes, a considerable proportion of the few candidates who applied for admission were men of such inferior attainments, that it was impossible to admit them. He moved the following resolutions—"That, owing to the successive changes in the Warrant of 1858, which gave general satisfaction, and to the practical departure from that warrant by the Executive, the medical profession have lost confidence in the good faith of the military authorities, and have, in consequence, ceased to apply for admission to the medical department of the army.

"That the frequent non-enforcement of the precedence granted by the Warrant of 1858, and its modification by the Warrant of 1863, which disqualifies the medical officer from presiding at boards (although on other than purely military matters), even when he is the senior officer present, have, by lowering his status, done more than any other grievance to deter the profession from joining the service."

Dr. Markham seconded the resolution. He hoped, however, that the meeting would not be satisfied with merely attacking what the Government had done. He had good evidence that much of the fault lay with the heads of the army medical department. The grievances to be amended were not only those which drove men from joining the army, but also those which were suffered by medical officers in the service.

Mr. Holmes Coote, having had an opportunity of witnessing the services of the army medical officers during the Crimean war, felt deeply for the grievances under which they laboured. As a lecturer in a large medical school (St. Bartholomew's), he had always exerted his influence with his pupils to prevent them from entering the army until the grievances complained of should be redressed; and, he believed, other lecturers acted in a similar manner. The idea had been expressed, that the diminution in the number of applications for the army medical service arose from a lessening in the number of students; this, however, was quite incorrect. The reason why more medical men did not enter the army was, that many other and more attractive fields of occupation were open to them. As to the annoyances to which army medical officers were subjected, he was well acquainted with them. The authority possessed by the army medical department was not sufficiently independent, and ought to be increased. He hoped that this meeting would be but the prelude to larger meetings of medical men for the purpose of advocating the claims of the army medical officers.

Mr. Gant supported the resolution.

Dr. G. Webster observed that on a former occasion—during the Russian war—the Branch had appointed a committee in regard to army medical matters. He had himself taken much interest in the matter, and had had an interview with the then Director-General, Dr. Andrew Smith, who acknowledged to him that, although nominally director, he had four or five masters. The result of the inquiry of the parliamentary committee had been to find that the disasters of the Crimean war did not arise from the fault of the medical officers, but from the manner in which they were impeded by other departments. As to the effect produced by the Branch Committee, he believed that, out of about eight or ten grievances pointed out by a

deputation to Lord Panmure, six or eight had been amended in the Warrant.

The resolution was carried unanimously.

Dr. Sieveking moved—"That, in the opinion of this meeting, in future the warrants which express the terms of service under which medical men enter the army shall be perfectly defined, so that no misapprehension can arise; and that no alteration shall be made in such warrants without an inquiry, which shall be open to the medical service, of the same extent and care as that which led to their first promulgation; and, moreover, that any such alteration shall be made with formality and publicity, and after an explanation to the medical officers of the grounds on which it has been considered necessary to alter the terms of service." He believed that the army medical service was generally entered for the purpose of avoiding the harass of ordinary practice; and, unless a medical man in the army could have a proper position secured to him, he lost all that for which he entered the service—for his pay and provision were but small, and his means of bringing up his family were limited. If, too, the value of the British soldier were remembered—a value which exceeded that of the soldiers of other nations—we ought to take care that the army medical officer was properly supported. He held that it was the privilege and duty of himself and the meeting, not only as members of the British Medical Association and as medical men, but also as Englishmen, to support any measures which aimed at improving the condition of the medical officers of the army.

Dr. Webster seconded the resolution, which was carried unanimously.

Mr. W. Martin proposed the following resolution—

"That, in the opinion of this meeting, the Warrant of 1858 should be the basis of future regulations for the Army Medical Department, subject to the following modifications:

"1. The proper definition and enforcement of the precedence of the medical officer, in accordance with his rank, at boards, mess, and committees of all kinds.

"2. Increased pay of assistant-surgeons and surgeons.

"3. Promotion to the rank of surgeon after, at most, ten years' full-pay service.

"4. Optional retirement after twenty years' full-pay service on an adequate pension.

"5. Controlling power and free agency in his own department, especially in times of emergency.

"6. Regular leave for medical officers, and sick leave on the same footing as is granted to all other officers.

"7. Non-deduction of pay for expenses incurred in the execution of his duty.

"8. The abolition of the system of 'confidential reports' on the conduct of medical officers.

"9. That all punishment inflicted by order of the military authorities should be carried out by them; the medical officer's duty on such occasions being limited to the protection of the soldier."

Mr. Martin said he would enter into but few details. There were two warrants at present in operation; that of 1858, which had been partially altered; and that of May 1st, 1863, which had been substituted for the seventeenth clause of the warrant of 1858. He read the clause and the new warrant; and observed that, while the former was clear and precise, the latter was very unintelligible, and appeared to deprive the medical officer of the presidency, not only of courts-martial (which no one wished him to have), but of boards of all kinds. This was the first point suggested for improvement, and it was very important; but he feared that the medical officers of the army would not now be contented with such a simple redress of grievances as would have satisfied them in 1860. The pay of assistant-surgeons might be sufficient at the commencement; but it was not so for them, nor for surgeons, when they had been some time in the army. With regard to the third point, he observed that promotion was sometimes very rapid, at other times very slow; and must always be retarded if made dependent on the occurrence of vacancies. If, too, a reduction in the army medical staff were made, the chance of promotion would be thereby diminished. It was therefore suggested that, in all cases, promotion should take place after a maximum period of ten years' service. The question of retirement was a very important one. Medical men entered the army late in life, as compared with ensigns; but were required at present to serve twenty-five years. The importance of the sixth recommendation was evident. As to leave, it was a very great grievance that, from the small number of medical officers in the service, leave could not be obtained by them. The army medical officer was, he considered, specially entitled by the nature of his duties to fixed terms of leave, and especially to a more liberal allowance of sick-leave. The explanation of the seventh recommendation was that, in many cases, where extras for the sick soldiers had been ordered by the medical officers, these had been disallowed on frivolous pretences, so that the medical men were fined for expenses incurred by them in performing their duty. As to the eighth recommendation, a system of confidential reports on the conduct, sobriety, &c., of the assistant-surgeons, was expected to be carried on by the surgeons; but this was often thought to be so great an injustice and hardship, that many surgeons had refused to perform it, and had consequently fallen into disfavour. The ninth and last recommendation was intended to include the operation of branding deserters, which was required to be performed under the superintendence of the medical officer. The special points to be borne in mind were: first, that the rank of the medical officer ought to be strictly defined; and secondly, that, as the soldier was entitled to the best surgical aid, every means should be taken to ensure this for him.

Dr. Henry seconded the resolution, which was unanimously carried.

Mr. Martin also moved, and Dr. Henry seconded, the following resolution, which was carried unanimously:—

"That it is deemed inexpedient that the systematic employment of deputy or acting assistant-surgeons without examination be continued; since it will inevitably introduce an inferior class of medical men into the service, and at the same time inflict great hardship on the military medical officer by increasing indefinitely the period of foreign service; and so still further deter medical men from entering the medical department of the army."

Mr. Propert moved, Mr. Henry Lee seconded, and it was resolved—

"That every means should be taken, through the medium of the military journals, and otherwise, to explain to the combatant officers that, if they desire to secure, for the promotion of the soldier's welfare, the services of the better members of the profession, they must receive as one of their own body, and cease to treat with jealousy, the medical officer who, equally with themselves, is a gentleman, and is exposed in time of war to the risks of the field."

Mr. Lord moved, Dr. Harley seconded, and it was unanimously resolved—

"That these resolutions be embodied in a memorial, to be presented (as a petition) to the Houses of Lords and Commons, and to the Prime Minister, the Secretary and Under Secretary for War, the Commander-in-Chief, and the Director-General of the Army Medical Department; and that the members of both Houses be personally requested to support the prayer of the petition.

"That these resolutions be communicated to the Executive Committee of Council; and that the other Branches of the Association be invited to take early steps towards the promotion of the movement."

Dr. Camps proposed, Mr. Gant seconded, and it was resolved—

"That the Council of this Branch be requested to carry into effect the resolutions carried by the meeting."—'British Medical Journal.'

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

APRIL 6TH, 1864.

DR. OLDHAM, PRESIDENT.

The following gentlemen were elected Fellows: J. M. Granville, Esq., Dr. J. F. Leeson, Dr. H. C. Phillips, and Dr. A. Wynn Williams.

Dr. OLDHAM exhibited an ovarian tumour removed from a lady under his care by Mr. Spencer Wells.

Dr. GREENHALGH exhibited a specimen of simple hypertrophy of the cervix uteri, removed by the wire rope écraseur.

After some remarks by Dr. HICKS and Mr. BAKER BROWN,

Dr. RITCHIE exhibited, and described the mode of using, Dr. Braun's cephalotribe and perforator.

Dr. BARNES considered it an objection to the perforator that it required two to work it, and was complicated. He thought the cephalotribe of Dr. Braun better than the French, and that the instrument had been perhaps too much overlooked in this country.

Dr. GRAILY HEWITT showed a cephalotribe from Paris, used by Pajot, which he considered more simple than Braun's.

SPONDYLOLISTHESIS; WITH AN ACCOUNT OF A CASE OF PELVIC CONTRACTION, IN WHICH PREMATURE LABOUR WAS INDUCED BY THE AUTHOR'S METHOD.

Dr. ROBERT BARNES read a memoir which embraced a history of the literature of this affection and a summary of the cases hitherto recorded. It was first described in 1853, by Kilian, who defined it as a slipping downwards and forwards of the last lumbar vertebra upon the sacrum, so that one or more of the lumbar vertebræ fall into the cavity of the pelvis, encroaching upon the space required in labour. In several cases the Cæsarean section had been necessary in order to deliver. The author added a case in which he believed this form of distortion was the cause of difficult labour. A woman, previously healthy, had been injured in the back. Considerable contraction of the pelvic brim followed. There was a marked depression in the lumbar region, and a projection internally above the promontory of the sacrum. Dr. Barnes brought on labour by his method at about the eighth month. The child was extracted by turning with some difficulty, still-born. The entire labour occupied less than five hours. The mother recovered. The remainder of the memoir was devoted to the discussion of the causes of the deformity, concerning which very conflicting views were entertained in Germany.

Mr. W. ADAMS observed that he had listened to the paper with great interest, as the vertebral deformity or displacement described was but little known, and required further investigation. It seems to him that the condition described as spondylolisthesis might depend upon several causes. Rickets might give rise to it; but this would be at once apparent by the general evidences of rickets in the development of the skeleton, distortion of the legs, &c. Caries of the first sacral bone might give rise to it; and some years after destructive disease had ceased, and anchylosis produced, the prominence forward of the last lumbar vertebra might encroach considerably on the pelvic cavity. Mr. Adams had seen a few examples of this, and had one now under his care at the Orthopædic Hospital. In this case the girl presented extreme lordosis in the lumbar region, with corresponding projection of the stomach, and a sharp posterior angular prominence corresponding to the first and second sacral bones. In all probability this girl, now twenty-one years of age, could never have a living child, in consequence of the projection of the last lumbar vertebra into the pelvic cavity. Congenital dislocation of both hip-joints produces extreme lordosis in the lumbar region, and, therefore, would probably give rise to the condition described as spondylolisthesis; and Mr. Adams had also seen it produced to some extent by a sharp rotation movement, and lateral distortion affecting the lower lumbar vertebræ, as in a case described by him in the 'Medico-Chirurgical Transactions,' vol. xxxvii. It was evident that a variety of causes might produce the vertebral displacement mentioned by Dr. Barnes, whose analysis of the cases recorded in the paper would form the basis of further observations on this subject.

Mr. BRODHURST observed that this was a subject which had not received much attention in this country. He considered that the affection in question was not a true dislocation, as it was described by the author of the paper, and that it differed materially from ordinary lordosis, and from those forms of lordosis which are produced by congenital dislocations of the heads of the femurs by some very rare forms of caries of the bodies of the vertebræ, &c.; but it was induced, he said, by softening of the bodies of the vertebræ, and especially by softening and yielding of the ligaments which unite the lumbar vertebræ and the sacrum. Thus was occasioned some displacement of the bodies of the lumbar vertebræ downwards. The positions of the spinous processes showed that caries was not the cause of this affection, as had been suggested, and a section of the bodies of the vertebræ showed this fact still more clearly. He contended that this condition was due to rachitic inflammation and softening of the osseous and ligamentous structures.

Dr. BARNES said that in studying the subject he had felt the want of a more extended practical knowledge of diseases of the bones than he possessed, and was therefore glad to have the assistance of Mr. Adams in discussing it. He was quite prepared to believe that caries of the upper part of the sacrum might cause the deformity. It was one cause, and did not exclude the possibility of other causes; nor did he gather from Mr. Adams's observations that that gentleman regarded caries as the sole cause. The case of the child figured by Robert, of Coblenz, was not an undoubted case of spondylolisthesis; and he was much interested in the suggestion of Mr. Adams, that the deformity was probably due to disease of the hip-joints, causing extreme lordosis of lumbar vertebræ without dislocation. He wished it to be borne in mind that this deformity consisted in a real slipping down of the fifth lumbar vertebra from the sacrum. It was a true dislocation, and not simply a curvature, of the spine. It was seen quite independently of rickets. It caused serious obstruction to labour, even in cases where the pelvis itself was free from distortion. He believed that this and other vetebral deformities possessed a great obstetric interest, and would, when more attention was directed to the subject, receive further illustration.

OBITUARY.

THE LATE MR. CARTWRIGHT, F.R.S.

(From the 'Medical Times and Gazette.')

Although we believe that the late Mr. Cartwright was never actually a member of the Medical Profession, yet he was so successful a cultivator of one of its auxiliary branches, and deserved so well of us by his magnificent hospitality, that we cannot allow him to pass away into the ranks of the departed without one word of commemoration. Even the youngest members of our profession must have heard of Cartwright, as the most celebrated dentist of his day, whose doors were besieged by crowds of the aristocracy, and who realised a princely fortune. His fortune, too, was not merely saved, but enjoyed. His hospitalities were on the most princely scale. It is well-known that when Paganini, the celebrated violinist, was in London, thirty years ago, creating a *furore* amongst fashionable *virtuosi*, Cartwright issued cards for an ordinary dinner party. When the guest arrived at the well-known door in Burlington street, the porter announced, with his master's compliments, that an accident had happened in the kitchen, so that he must take the liberty of asking them to come on to the Clarendon close by, where he proposed to receive them. On they went accordingly, and then were conscious of the friendly artifice of their entertainer, who had taken this method of gathering together a much larger number of

guests than his own dining-room could accommodate, and then, after a most sumptuous entertainment, produced Paganini, who gave them a private exhibition of his musical skill. There is a moral of a very homely sort to be drawn from Mr. Cartwright's life, which we venture to impress upon our young readers. Some young men are apt to fancy that a fine figure, and flattering tongue, and ostentatious *ménage* may enable them to "get hold of the aristocracy," and make fortunes by adulation and other arts of humbug. That which led to Mr. Cartwright's rise and success was the direct contrary. He was a plain-looking, quiet man, who made his own way by simple means; he used the greatest industry in his profession; he strove to do everything in the best way; he got the credit of doing things better than any one else (and there could be no mistake where teeth were concerned); then, without running after success, success came to him. The writer of this notice well remembers that when a student, some years ago, he happened to be breakfasting with a well-known Professor, who, in the course of talk, said, "I'll tell you something that should be a model to you. Last night we elected Cartwright, the dentist, an F.R.S. There was a kind of row about it; some men said he ought not to be elected, but most of us felt that he was a very good fellow, and we carried him; and look here, here is his card; he called on me this morning before eight, and left his card in acknowledgment. That is the way to get on in the world. Be prompt and punctilious in acknowledging the slightest benefits. This shows you how Cartwright got on." So said our Mentor, who has now long since preceded us into the region of shadows. We bear witness to the benefits of Cartwright's splendid entertainments; how they brought men together, smoothed off asperities, cemented friendships, and gave some poor struggling scientific men a glimpse of the brighter side of life. When the recording angel sums up, and strikes the balance, we are sure that he will remember to Cartwright's credit that to be "given to hospitality" was pronounced on the highest authority to be a virtue even in a bishop.

PROFESSOR MILLER OF EDINBURGH.

We regret to announce the death of Mr. James Miller, Professor of Surgery in the University of Edinburgh, which took place at Corstorphine on Friday last, at the age of fifty-two. The deceased gentleman was the son of the late Rev. James Miller, minister of Monikie, in Forfarshire. He studied medicine in Edinburgh, and was the favourite pupil of Mr. Liston, with whom he resided for fifteen years—for five years as his assistant, and who, before leaving Edinburgh for London, introduced him to all his patients. In 1842, on the death of Sir Charles Bell, Mr. Miller was unanimously elected by the Town-Council to fill the Chair of Surgery in Edinburgh University, where he was a very popular and successful teacher. Mr. Miller was also Professor of Pictorial Anatomy to the Royal Academy, and was Surgeon-in-Ordinary to the Queen for Scotland. As a consulting surgeon his services were highly esteemed, and both in the scientific and practical parts of his profession he maintained a high reputation. He was the author of 'The Principles and Practice of Surgery,' which has passed through four editions in this country, and been several times reprinted in America. He was also the writer of the article "Surgery" in the 'Encyclopædia Britannica'; and the author of 'The Surgical Experiences of Chloroform,' and other works. He published a considerable number of tracts on temperance, of which he was a strenuous advocate. In philanthropic and religious agitations he took a very active part, both on the platform and through the press; and as an elder in the Free Church was an ardent supporter of its politico-ecclesiastical views, and of its missionary schemes. He was a man of lively and generous sympathies, and of kindly temper, and he enjoyed the affection and esteem of a wide circle of friends, accompanied by no small degree of popularity in public life. He was a man of fine *physique*, and the sudden breakdown of his constitution gave a shock of surprise to many who had admired his manly vigour and envied his robust health. A few weeks ago he was seized with congestion of the brain, which, notwithstanding the most watchful care of his professional friends, entirely prostrated his strength, both mentally and physically, and rapidly led to a fatal result. Professor Miller married in 1834 a daughter of the late Major Gordon, of Rosiburn, Aberdeenshire, who, with a numerous family, survives him.

DEATHS.

BEWS.—On the 8th ult., at Jersey, J. H. Bews, L.R.C.S.I., Staff Surgeon Army.

FREEMAN.—On the 27th ult., T. D. Freeman, Surgeon, formerly of Leigh, Worcestershire, aged 69.

MACDOWALL.—On the 10th inst., at Helensburgh, Dumbartonshire, Alex. A. Macdowall, M.D.

PENNINGTON.—On the 6th inst., at Needham Market, Suffolk, James Pennington, M.R.C.S.E.

SMITH.—On the 5th inst., at the Rectory, Richmond, Yorkshire, E. Smith, M.D., of Ilkley Wells House, near Otley, Yorkshire, aged 59.

WALLACE.—On the 8th inst., at Morningside, Edinburgh, Wm. Wallace, M.D., late 14th Regiment of Foot.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 9th inst.:—Henry Todd Broughton, Bradford, Yorkshire; John Holden, Ardwick and Ancoats Dispensary, Manchester; Edward Maundrell, Rutland street, Hampstead road; George Edmund Legge Pearse, Regent street, Westminster.

The following gentleman also on the same day passed his first examination:—Charles Meymot Tidy, London Hospital.

UNIVERSITY OF CAMBRIDGE.—DOWNING COLLEGE.—At a meeting of the Master, Professors, and Fellows, on the 10th instant, the following elections took place:—Collins and Schrœder, to foundation scholarships of 50*l.* a year with rooms and commons; * Brailey, † Hare, * Lankester, and ‡ Payne, to minor scholarships of 40*l.* a year. 20*l.* was awarded to Dickson for distinction in Natural Science. At the same meeting it was agreed that a chemical laboratory should be built upon the College grounds for the use of Students in Medicine and Natural Science, and be placed under the superintendence of Dr. P. W. Latham.

* Distinguished in Natural Science. † Distinguished in Classics. ‡ Distinguished in Law and French.

THE AMERICAN MEDICAL ASSOCIATION.—Every medical man, solicitous for the honour, dignity, and progress of his Profession, seems cordially to welcome the return of the annual meetings of the American Medical Association. Like the French and English national associations, it gives compactness and uniformity to the great mass of medical minds, and concentrates their sympathies and efforts on all reforms and improvements. But the American Medical Association serves a still higher and nobler purpose than other similar societies. It is our Court of Appeal in all questions relating to medical ethics, the status of schools, individuals, voluntary organizations, &c., &c. Such an organization is eminently necessary to preserve the integrity and harmony of the Profession. England has its Medical Council, which under the statute legislates with the power of a corporate body, and this is in accordance with her institutions. But the nearest approach to such a medical governing body we can attempt, is a voluntary organization which carries sufficient inherent moral force to render its decrees binding. Such is the position attained by the American Medical Association, and such is the character with which every one should strive to clothe it; to this end we must foster its growth, and the extension of its influence. Every question affecting the great body of the Profession, and every cause of dissension that cannot be settled by local societies without creating discord, should be referred to this body, and its decisions should not only be respected but faithfully followed. Thus the Association will truly become a great National Medical Congress in

which every interest is represented, and whose annual legislation will elevate, purify, and strengthen the Profession, and bind more closely the bonds of fellowship.—'American Medical Times.'

PRINCELY BENIFICENCE.—The Hon. Rustomjee Jamsetjee Jejeebhoy, member of the Legislative Council of Bombay, son of the late Sir Jamsetjee Jejeebhoy, placed some time since at the disposal of Mr. Crawford, M.P. for London, the sum of 15,000*l.* for the purpose of appropriation to charitable purposes in London, in connexion with the name of his late father, more especially the charities of the city of London, of which his father was a freeman, under the following condition :—"The charities selected to be those which have in view the alleviation of the wants of the poor and indigent, the infirm and helpless, and not societies which are of a religious character." The charities so selected are enumerated in the following list, the ruling principle of the appropriation being the selection of those institutions whose doors are always open to every class of sufferers on the instant, without reference to any other consideration than the merits or urgency of the particular case in need of help. The appropriation to the London Hospital is in connexion with the new wing, of which the foundation-stone is to be laid on the 4th of July by the Prince of Wales, and the fact that the London is pre-eminently the hospital of the commerce of the port of London. Amongst the medical charities which will derive benefit from the princely munificence of the great Bengalee benefactor are the following:—Hospitals.—London, 2,000*l.*; University College, 1,000*l.*; Metropolitan Free, 1,000*l.*; Royal Free, 500*l.*; Middlesex, 500*l.*; King's College, 500*l.*; London Fever, 500*l.*; City of London, for Diseases of the Chest, 500*l.*; for Sick Children, 500*l.*; Royal, for Incurables. 400*l.*; British Home for Incurables, 400*l.*; Asylum for Idiots, 400*l.*; for Diseases of the Skin, 300*l.* : total, 8,500*l.* Dispensaries.—City, 500*l.*; Farringdon, 500*l.*; City of London and East London, 400*l.*; Royal General, 400*l.*; Metropolitan, 400*l.*; Western City, 200*l.*; Finsbury, 200*l.*; City Orthopædic, 200*l.*; Queen Adelaide's Dispensary, Bethnal green, 200*l.* : total, 3,000*l.*

AID TO THE WOUNDED IN AMERICA.—The Volunteer Corps of Surgeons from New York and the States in the vicinity have readily responded to the call for aid to the wounded in the recent battles of the Army of the Potomac, and are now rendering efficient service at Fredericksburgh, Belle Plain, and Washington. The number of wounded, however, is increasing from day to day, and the need for even more help is very urgent. A great many additional surgeons have volunteered their services and there is still work for more. We hope that the supply will be equal to all demands, that numbers will avail themselves of the opportunity for doing a good work by giving every aid in their power, and relieving those who are already there, and who, ere this, are worn out by arduous services. The Surgeon-General of this State, Dr. Quackenbush, has recently been in the city to perfect arrangements for sending on all the additional help which may be called for, and too much praise cannot be given him for the manner in which he has performed his duties. We have great confidence in the workings of the volunteer system, and think it safe to say that the assistance which they will be enabled to furnish their brethren in the field cannot be lightly estimated. We understand that there is also a want for younger men in the hospitals around Washington, and we need not urge those who are anxious to study their profession to improve the opportunities which are now offered them.—'American Medical Times.'

A FRENCH MEDICAL MUTUAL BENEFIT SOCIETY.—The Dean of the Faculty of Paris, Dr. Tardieu, has had the felicitous idea of establishing a mutual benefit society among the students of medicine. This scheme, which has met with the cordial sympathy of the Profession, is now in course of realization; and we seize this opportunity of assenting to the unanimous approbation expressed in the medical periodicals. A public and general meeting of the students was called by the Dean on the 24th of April, in the principal amphitheatre of the School of Medicine, and large numbers were present. Professor Tardieu stated that he had already received 652 adhesions, and gifts and subscriptions to the amount of 242*l.* He then briefly described the systems adopted by various mutual benefit societies, and the respective advantages of each, and stated that the object of the present meeting was the nomination of a committee for the preparation of rules and regulations subsequently to be adopted after discussion. The Dean remarked that the students were now called on to manage their own affairs, and to secure the prosperity of an institution, the utility of which they had appreciated from the first. He observed, in addition, that he was empowered to offer the assistance and advice of gentlemen of liberal tendencies, and well versed in all questions connected with the subject of associations, Messrs. Paul Andral, Balbie, and Paul Bethmont. The Dean expressed his own readiness to be present at the meetings of the committee, not for the purpose of influencing its decisions, but merely to offer the assistance of his experience and efforts. A debate ensued on the mode of voting, and on the impossibility of electing the committee without previous agreement. The discussion was animated, but perfectly courteous and moderate, and terminated in the adoption of the following resolution: "The number of the members of the committee is limited to fifteen." The election took place by ballot on the 1st of May. The following gentlemen have already entered their names as subscribers: Mr. Louis Veron, the well-known journalist, forwarded 500 francs, and Messrs. Mialhe, Roger, and Diday each presented a similar sum. The Dean has, moreover, received from an anonymous contributor 40*l.*, with the following designation :—"*For services rendered by Mr. Tardieu.*"—'Journal of Practical Medicine and Surgery.'

PROPOSED MEMORIAL TO SIR HUMPHRY DAVY.—On Friday, the 10th inst., a numerous and influential meeting was held at Penzance to promote the erection of memorial almshouses and a statue to the memory of the late Sir Humphry Davy. The proposal originated, about three years ago, with some working men, who thought that the inhabitants of Penzance ought to pay some tribute to their great fellow-townsman. Subscriptions, however, were received but slowly, until, about three months since, a lady generously volunteered 1,000*l.* for the purpose. The Chairman, Mr. William Coulson, of Kenegie, the distinguished London surgeon, himself a native of Penzance, in an eloquent address recounted most interesting particulars of the life of Davy, and gave an elaborate and striking description of the claims of the great chemist to the respect and honour of his townsmen. The mayor and several other gentlemen ably supported the object of the meeting, and there is no doubt that the result will be worthy of the great man to whom science is so much indebted. That the Chairman had peculiar claims to the position which he so worthily filled was proved by Mr. W. D. Mathews, who, in moving a vote of thanks to him, said that "by his eloquence he had fulfilled the phrase of 'the right man in the right place.'" He had promptly responded to the invitation from the working men of Penzance, and they had seen how much they had reason to be indebted to him. Sir Humphry Davy was a personal friend of the father of the chairman. Mr. Thomas Coulson was in business in Penzance until 1803, when he lost his wife, and desired to obtain a situation under Government. Through Sir Humphry the appointment was got, and in answer to a letter of thanks Sir Humphry wrote a letter, the original of which he held in his hand, and which concluded—"You cannot well be in London too soon. When I see you I will discuss the business more fully. I am heartily glad that my labours in your behalf have been successful. There is no pleasure in life greater than that of finding free scope for the most active part of the most powerful mind. Yours sincerely, HUMPHRY DAVY." These were facts worth mentioning, and which the chairman would not, perhaps, have referred to. It was a fact too, that Mr. John Bingham Borlase, with whom Sir Humphry Davy was apprenticed, was a maternal uncle of Mr. William Coulson, of Kenegie, their chairman.

THE PAY OF ACTING ASSISTANT-SURGEONS IN AMERICA.—On account of the present depreciation in paper currency,

the pay of our surgeons is necessarily narrowed down to quite a small figure, and the acting assistant-surgeons, who, as far as remuneration is concerned, are at the bottom of the list, necessarily suffer the most. This being the case, we can easily understand why the demand for this class of medical labourers is still urgent. Until the government chooses to increase the pay, it cannot expect to have its wants supplied. No respectable practitioner can, for simply a hundred dollars a month, be tempted to leave his business for any length of time, even for temporary service; and the hospitals of the country will necessarily soon get filled with young irresponsible medical striplings. If the government wishes first-class men, it must pay first-class prices.—'American Medical Times.'

MEDICAL STATISTICS AND CHLOROFORM.—Sangrado was described wittily as a man who used his patients as a vintner does his wine vessels, by letting out their blood and filling them up with water: he was only following the lancet routine of his day. Roger Bacon places, indeed, the chief impediment to the progress of knowledge in the world in the influence of authority. Yielding to such seductive influence, however, we have had this

"Macies et nova febrium
Terris incubuit cohors,"

this chapter of horrors, where everything ever said against chloroform has been curiously and industriously compiled. I would only say, in conclusion, as to statistics and medical prejudices, but open to conviction otherwise, that I very much doubt the alleged great value of the "numerical method" as at all applied to this subject of the use of chloroform in midwifery. Chloroform is a matter of charity to the woman in labour, and I would as soon be led by figures in giving charity to a destitute man in the street or to a ragged school: it is also perfectly free from danger. Even since I came to understand the medical statistics of the Registrar-General in England, to meet popular prejudices on such subjects as chloroform, change of type in disease, danger of feeding prisoners in gaols on too much bread and water, for fear of increasing crime and sthenic inflammations, the danger of wine in typhus, &c. When we know that as in the figures in a wall-paper the weekly statistics are filled in always to the same pattern, one ceases to have much faith in figures. I know there is not one well-attested death from chloroform in midwifery in all our journals; three such cases have recently been quoted, or alleged in America from England; but I have examined into the cases: in one, for instance, the death occurred seventeen hours after the patient had perfectly recovered from the chloroform; she died of laceration of the vagina, from crotchet or forceps. And so of the others. "All superstitions," says John Stuart Mill, "are inductions of the Bacon kind; and we have venerable popular inductions of this kind, not to be disturbed, that chloroform is most fatal in midwifery. Insurance actuaries, who know nothing of medical prejudices one-sided and journalistic, are the only men who get any good out of medical statistics. If we visit the accidents of crotchet or forceps on a thing running parallel with them, namely, chloroform, it is not fair or logical. I am willing to give Dr. Johns the benefit of his inductions or hasty generalizations; but he surely ought to know that they are but coincidences after all. I had a conversation once with M. Quetelet, at Brussels, on medical statistics. "They are but finger-posts in the cross-roads of medical journalism," said this deep observer. We have parallel roads too—I often think parallel lines—that have no connexion, that never touch; and some such are the alleged facts I have felt it my duty to comment on. We compare a few of the worst cases requiring chloroform for versional deliveries, or instruments, or puerperal convulsions, with others (16,414) of much less gravity, where chloroform was not required (for chloroform, it must be remembered, is not given as a luxury or charity in hospitals, but as a necessity). We have taken as a standard this (1 in 100) one per cent. of deaths in a healthy year of a mass of simple labour cases in the early part of the present century, when the population of Ireland were well fed and nourished, and nature effected the cure, and, no doubt, without chloroform; and we have contrasted this standard with a higher mortality in an unhealthy year, then the Irish population deteriorated, puerperal fever epidemic.—Dr. KIDD, in 'Dublin Quarterly.'

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JUNE 22.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, Caledonian road, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, JUNE 23.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, JUNE 24.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, JUNE 25.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

MONDAY, JUNE 27.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JUNE 28.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Selections from Physicians' Prescriptions. By Jonathan Pereira, M.D., F.R.S., &c. Fourteenth edition. London: John Churchill and Sons, New Burlington street.

Contributions to Practical Medicine and Surgery. By James Arnott, M.D. London: John Churchill and Sons.

Entoptics; with its Uses in Physiology and Medicine. By James Jago, M.D. London: John Churchill and Sons.

A Companion to the British Pharmacopœia. By P. Squire, Esq., F.L.S. London: John Churchill and Sons.

The Principles and Practice of Medicine; designed chiefly for Students of Indian Medical Colleges. By John Peet, M.D., F.R.C.P., Principal and Professor of Medicine, Grant Medical College, Bombay. London: Churchill and Sons. Bombay: Thacker, Vining, and Co. 1864.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

MR. SQUIRE.—The book has been received.

DR. H., *Cambridge*.—The letter has been received.

THE OBSTETRICAL SOCIETY.—The report has been received.

A SUBSCRIBER.—The 'Social Science Review' is published at 10 Whitefriars street, Fleet street, London, E.C. The first number of the present series appeared on January 1 of the present year, and the price of each monthly number is one shilling.

EDINENSIS.—We have read the account of the trials alluded to, and should feel obliged by some further particulars. The points raised are very important.

INSPECTOR-GENERAL.—It is not likely that the College will take any active steps in the matter.

MR. E. H. MOORE'S letter shall be inserted next week.

THE HARVEIAN SOCIETY.—The report has been received, and shall appear next week.

A VESTRYMAN.—We are sorry to be unable to give a perfectly satisfactory answer to the question put to us. Only a graduate of a University can legally call himself a Doctor of Medicine, and a member of the College of Physicians of Edinburgh has no legal right to that title. The gentleman named *is* a graduate of a University. Many persons style themselves Doctor, or are so styled by their friends, who have legally no right to the title.

BARTH'S OXYGEN WATER

HOLDS FREE OXYGEN IN SOLUTION,

gently stimulates the functional action of the stomach and secretory organs, and is a very pure useful beverage. WENTWORTH SCOTT's Analysis gives as contents of a bottle—"Nearly half of an imperial pint of distilled water, and about 13·5 cubic inches, or 4·6 grains of gaseous oxygen; equivalent to that contained in 21·4 grains of chlorate of potash."—4s. per dozen.

OXYGENATED WATER COMPANY (LIMITED), 36 LONG ACRE.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

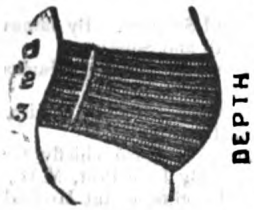
where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 73 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms, Elliott, and other eminent makers.—Catalogues forwarded on receipt of Stamp.

BLOCKEY'S LONDON STOUT

NOURISHING LONDON STOUT

DR. HASSALL'S REPORT:—"I have carefully analyzed Blockey's well-known Stout, as obtained from 21 Duke street, St. James's, and find it to be a genuine, most wholesome, and highly nourishing beverage, less heavy, and consequently more digestible than London Stout in general.—Signed, ARTHUR HILL HASSALL, M.D London, Analyst of 'The Lancet' Sanitary Commission." Casks of 4½, 6, 9, and 18 gallons, at 1s. 8d. per gallon; 3s. per dozen pints; 5s. quarts.



RAGGETT, late Blockey, 21 Duke st., St. James's. Established 100 years.

Pulvis Jacobi ver, Newbery

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

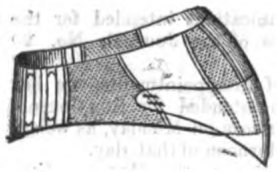
Prices for Dispensing—1 oz., 9s.; ½ oz., 3s. 4d.

MR. P. BOURJEAURD'S REGISTERED SPIRAL ELASTIC

BANDAGES, to be obtained only at No. 11 DAVIES STREET, BERKELEY SQUARE, W., and No. 11 RUE DES BEAUX-ARTS, PARIS.

Mr PHILIP BOURJEAURD, in submitting the accompanying diagrams, presents his best thanks to those Gentlemen who have, for some years past, prescribed his appliances in cases indicating their necessity, and begs respectively to assure others, who have not used them in their practice, that they will find them a most valuable assistance in most cases indicating their necessity of compression or support. The inventions consist of Abdominal Supporters, Hernia Apparatus, Ankle, Knee, and other Bandages, with various other Appliances, that the élite of the Profession have pronounced to be most ingenious.

N.B.—No. 11 DAVIES STREET, BERKELEY SQUARE, W., near Mivart's Hotel. The establishment is strictly private, not having any show of Bandages in the window. A highly-respectable married female to wait upon Ladies, who may insure her attendance in Davies street, or at their own establishments, by favouring Mr Bourjeaurd with instructions according to their own preference.—Poor Patients are supplied at a reduction of thirty per cent. lower than the imitations.



AT HOME FROM TEN TILL SIX.

J. & E. BRADSHAW,

LATE

SHOOLBRED AND BRADSHAW,

34 JERMYN STREET,

Beg to call attention to the various improvements in Patent ELASTIC STOCKINGS, BELT, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera and the cure of Rheumatism, Lumbago, &c.

*** Every description of INDIA-RUBBER BANDAGE, vulcanised on the newest principle. Directions for Measurement sent by post.

N.B.—A Liberal Discount to the Profession.—A Female to attend on Ladies.

H. Silverlock's Medical Label Ware-

house, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctors Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.

YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.

SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.

LABEL DRAWERS, for Dispensing Labels of various sizes.

A Set of Labels in accordance with the 'BRITISH PHARMACOPŒIA' now ready.

Pepsine and Pepsine Wine.—Boul-

DAULT begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Chemist in Ordinary to the Queen and H.R.H. the Prince of Wales, 227 Oxford street, London, to whom all applications respecting it must be addressed.

Third Edition, with Further Remarks by Dr. CORVISART, Physician to the Emperor of the French, edited by W. S. SQUIRE, Ph. D.; published by J. Churchill, London; may be also had of the Author, 277 Oxford street, price Sixpence.

Flour — (Essex) — Warranted free

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs.), 9s. 0d. Households (recommended for bread-making), 7s. 8d.; Seconds, 7s. 0d.; Wheat Meal for brown bread, 7s. 0d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

Whicker and Blaise, late Savigny

and Co., Wholesale and Retail Cutlers and Surgeons' Instrument Makers, No. 67 St. James's street, from Pallmall and King street, London, and at their Manufactory, Young's place, Wood street, Westminster

Microscopic Glass.—Thin Glass for

Mounting Objects, in squares or circles. Slides 3 in. by one in., and Cells of every kind, supplied Wholesale and Retail, by

CLAUDET and HOUGHTON, 89 High Holborn London.

N.B.—Aquariums, Fern Cases, and Glass Shades.

Medical Fixtures and Glass Manu-

FACTORY, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of HOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc.

Kamptulicon, Floor-cloth. — The

attention of the Medical Profession is requested to be given to the many advantages of this article as a floor covering, for the Wards of HOSPITALS, Surgeries, Nurseries, &c. It is non-absorbent, quiet and warm to the tread, will not hold dust, is very easily and quickly cleaned, and will stand any amount of hard wear. It has already been adopted in several hospitals.

GOUGH and BOYCE, 76 CANNON STREET WEST.

Original Patentees and Manufacturers.

Forwarded to all parts of the Country.

The Medical Circular.

HOSPITAL REPORTS.

KING'S COLLEGE.

OBLIQUE INGUINAL HERNIA.

J. B., æt. forty-two, admitted Feb. 8th, 1864, into the Fisk Ward, under the care of Mr. Partridge, suffering from strangulated inguinal hernia on the right side.

History.—Is married. States that he has been ruptured since he was ten years old, at which time he got a kick in this region—about the site of the right inguinal canal; to this kick he attributes the rupture.

When it first presented it was about the size of an egg, and continued so till about five weeks since, when, as he was walking along the street, he felt the rupture come down and at the same moment experienced great pain—so much protruded that it was in size equal to about two hands placed together in such a manner as with the fingers to form a circle. Immediately after this sudden prolapse he applied for relief at the hospital, and Mr. Pollock at once placed him in a warm bath and attempted reduction, but not succeeding, he had the patient put to bed, and then, while making a second attempt, succeeded in getting it up. The patient never wore a truss, because he never had felt any inconvenience; after this return of the hernia into the abdomen he wore a truss, but as it did not succeed in keeping up the protrusion he again applied to Mr. Partridge, who advised him to support it by means of pads and bandages. This he did for a few days, and then tried the truss again; he returned to his work, worked all day, and as he was walking the bowel slipped down again, and he could not get it back into the place. On applying for relief he was put into a warm bath and the taxis resorted to, but it failing, he was placed in bed and ice applied for an hour, after which reduction was effected. He complained of a severe cutting pain round his waist at the time of the prolapse; upon both occasions of the accident he had become sick. He has no children; none of his family suffer from rupture.

Mr. Partridge saw him on the Sunday when the rupture came down on the first occasion; on the second it came down on Feb. the 8th. He states that he was always able to get it back except on these occasions just noted.

Feb. 17th.—The patient placed under the influence of chloroform, Mr. Wood proceeded to operate for the radical cure.

He made an incision into the scrotum and dissected the skin from the subjacent tissues, which latter he invaginated by means of wire. After passing the wire, as usual, through the pillars of the ring and through the sac in front of the cord, he again introduced the ends through the pillars; pads were applied to make pressure on the walls of the canal under the wire, and the patient bandaged, &c., and sent to bed.

Feb. 18th.—Had some pain in the belly on the night of the operation, also flatulence and nausea. Was ordered pil. saponis co., gr. v., quarta quâque horâ and fomentations to the abdomen. The pain in the belly gets better at times. His tongue is coated.

Feb. 20th.—Large poultices over the wound in the belly. Dressings and pads removed.

Feb. 21st.—Ordered

Ol. ricini, ℥j.;
Ol. rutæ, ℥j.;
Decocti avenæ, Oi. ft. enema statim administr.

Feb. 22nd.—The enema has just given him relief; he has now no flatulence or sickness; his tongue is cleaner, and the sickness was checked last night. He slept pretty well; the pain in the abdomen is almost quite gone, and he enjoyed a basin of beef-tea.

Feb. 29th.—One of the wires removed. The discharge is quite healthy.

March 11th.—The second wire was removed three weeks after the operation. There is very little discharge, much consolidation, and no impulse on coughing.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XIX.

CALX AND CALCIS HYDRAS.—Lime is described in the Materia Medica as occurring in light lumps, externally of a dirty white colour, but white within. Lime varies somewhat in its characters in different parts of the country; but there are generally two varieties to be met with, namely, white lime and grey lime. The Pharmacopœia evidently intends the former, which is decidedly the purest, to be used.

The introduction of hydrate of lime into the Pharmacopœia as a distinct preparation is a decided advantage, for it affords the means of ordering the use of a purer and more definite substance than was possible in previous Pharmacopœias. When good lime is slaked with a proper quantity of water, it evolves much heat, which volatilizes a portion of the water as steam, crackles, swells up, and ultimately forms a fine light powder. There are always present, however, some had pieces which will not absorb the water, and also occasionally a few stones, pieces of cinder, &c. These could not be separated when, according to former Pharmacopœias, a quantity of lime was ordered to be weighed, then slaked and used. Now, however, we are in all cases directed to use hydrate of lime which has been previously prepared by the process given.

By this process two pounds of recently burnt lime are to be slaked with one pint of water. When the disengagement of vapour has ceased, the vessel containing the hydrate is to be covered until its contents are cold. Then the powder is to be passed through an iron wire sieve and preserved in a corked bottle.

By this sifting the unslaked pieces, the cinders, &c., will be separated, and a practically pure hydrate of lime having the composition CaO, HO will be obtained.

The impurities present in lime are carbonate, sulphate, and phosphate, with silica, iron, and alumina.

LIQUOR CALCIS AND LIQUOR CALCIS SACCHARATUS.—It is a remarkable peculiarity of lime that it dissolves to a greater extent in cold water than it does in hot. Mr. Phillips has given the following table of solubility:—

1 pint of water at	32°	dissolves	13·25	grs. of lime.
„ „	60°	„	11·6	„
„ „	212°	„	6.7	„

Consequently, water at the freezing point dissolves twice as much lime as it does when boiling. Lime-water is to be made by shaking up two ounces of slaked lime with a gallon of distilled water, and afterwards decanting the clear solution. Ten fluid ounces of this solution should require for neutralisation at least twenty measures of the volumetric solution of oxalic acid. In other words, ten ounces should contain 5·6 grains of lime, or 11·2 grains in a pint.

The quantity of alkali which can be thus dissolved is however, inconveniently small; Mr. Bastick therefore, some time back, introduced into Pharmacy a "Concentrated Lime-water," which has certainly proved a useful preparation. The Pharmacopœia has now adopted a similar solution, under the name of *Liquor Calcis Saccharatus*. It is well known, in fact, that lime is freely soluble in the solution of several saccharine principles, such as sugar, glycerine, mannite, sugar of milk, &c. In order, therefore

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

By Robert Hunter Semple, M.D.,

Member of the Royal College of Physicians of London, Senior Physician to the St. Pancras and Northern Dispensary, Physician to the Standard Life Assurance Company.

(Continued from page 392.)

Endocardial Murmurs.—Organic Murmurs.—Having previously pointed out the principal distinctions existing between murmurs arising from functional causes and those produced by organic disease, I next proceed to describe, as far as possible, the exact nature of the organic lesions which give rise to cardiac murmurs, and the special seat of disease which is indicated by those abnormal sounds heard on certain external parts of the præcordial region. In this department of practical medicine, a remarkable degree of accuracy has been attained; and thanks to the repeated examinations made and recorded during life, as compared with the appearances observed after death, the seat of disease within the heart may be determined almost as exactly as if the parts were exposed to view. But while the seat of the disease may thus be very accurately ascertained by stethoscopic examination, its extent or severity can unfortunately by no means be predicated with equal certainty, nor, as has before been remarked, can the loudness or the distinctness of a murmur be regarded as a necessary exponent of its pathological importance. All we can assert is, that the presence of a murmur heard at a certain time, or over a given spot, indicates very accurately both the seat of endocardial disease, and the nature of the obstacles which the blood encounters in its onward passage through the cavities of the heart.

It may be stated generally that organic cardiac murmurs arise from two distinct causes—namely, from the obstruction offered to the passage of the blood, or from its regurgitation through apertures which it has once already passed. The seat of these murmurs is now almost universally admitted to be the cardiac valves, although it was once supposed that the abnormal sounds might be caused by disease of the heart, independent of valvular lesion. The valvular affections giving rise to the murmurs may be classed under the two heads of *contraction* and *insufficiency*, the former condition offering an impediment to the flow of blood, the latter allowing the blood to flow back through the floodgates which ought to have arrested its progress.

By reference to the normal action of the heart and the synchronism of its movements, the significance of the morbid sounds will be easily appreciated. The murmur may be heard coincidently with the first sound, or with the second, or with both; it may be heard over the region of the aortic valves or over that of the mitral valves. These are the valves most commonly affected with disease, but it should be recollected that the pulmonary semilunar valves and the tricuspid valves *may* be affected also, and that the former lie on the same plane with the aortic valves, and the latter on the same plane with the mitral valves. The tricuspid valves, however, lie more on the right side than the mitral.

Now, a murmur heard with the first sound of the heart is synchronous with the contraction of that organ, and is consequently named a *systolic* murmur. At this period, in the healthy heart, the blood is propelled by the muscular walls of the heart through the orifices of the aorta and the pulmonary artery; and on the other hand, it is shut off from the cavities of the auricles by the closure of the mitral and tricuspid valves. But if the aortic or the pulmonary semilunar valves are contracted, or if the mitral and tricuspid valves are incompletely closed, then the blood will be obstructed in its passage through the first, and will regurgitate through the second. Therefore a murmur heard with the first sound of the heart will indicate either a contraction of the aortic or semilunar pulmonary valves, or an insufficiency of the mitral or tricuspid valves.

But if the murmur accompanies or replaces the second sound of the heart, it is synchronous with the dilatation of the organ, and is called a *diastolic* murmur. During the diastole, the blood is passing from the auricles into the ventricles through the mitral and tricuspid valves, while at the same moment the aortic and pulmonary semilunar valves are closed to prevent the reflux of the blood, which has been propelled by the ventricular contraction into the aorta and pulmonary artery. Hence, if the auriculo-ventricular orifices are contracted, and if the valves of the aorta and the pulmonary artery are insufficiently closed, the blood will be obstructed in the first case, and will regurgitate in the second. But practically it is found that a diastolic murmur almost always indicates an insufficiency of the arterial valves, because the blood does not pass through the auriculo-ventricular apertures with sufficient velocity and force to produce an audible sound.

Thus it has been shown that a murmur with the first sound indicates either contraction of the arterial or insufficiency of the auriculo-ventricular orifices; and a murmur with the second sound indicates an insufficiency of the aortic or pulmonary semilunar valves. The distinction will be drawn by reference to the region over which the abnormal sound is heard. The aortic and pulmonary semilunar valves are placed on the same level, and the mitral and tricuspid valves are also placed on the same level; but the level of the former is considerably higher than that of the latter, and hence it is now admitted as a general rule, that a murmur heard over the base of the heart indicates disease of the aorta or pulmonary artery, and that a murmur heard over or towards the apex of the heart indicates some morbid condition of the mitral or tricuspid valves. It should be further remarked that, when the aortic valves are the seat of disease, the murmur is often prolonged into the arteries; while in disease of the mitral and tricuspid valves, the murmur is more confined in its limits.

Thus, a murmur with the *first* sound, heard over the base of the heart, at the upper third of the sternum, and prolonged into the arteries, will indicate contraction of the arterial orifices; while a murmur with the same sound heard over the apex of the heart will indicate insufficiency of the mitral or tricuspid valves. A murmur with the *second* sound, which is usually heard only over the base of the heart, indicates a disease of the aortic valves, and affords evidence of insufficiency of those structures.

"In the majority of cases," says Dr. Bellingham,* whose remarks are borne out by general observation, "the *bruit de soufflet* is heard at the period of the ventricular systole, and replaces or accompanies the first sound of the heart; the force with which the blood is propelled by the left ventricle being much greater than that with which it enters it, the friction between the blood and the parts along or through which it passes must be much more considerable during the former action than the latter. In the former it is generally sufficient to generate a murmur, in the latter it only occasionally does so; and when a murmur is developed, it has a different character. For instance, when the mitral valve or orifice is diseased, so as to permit regurgitation, a *bruit de soufflet* will be heard at the period of the ventricular systole, which quite obscures the normal first sound of the heart; when the aortic valves permit regurgitation, a *bruit de soufflet* is audible at the period of the ventricular diastole, which likewise obscures the normal second sound of the heart. But the two murmurs have a different character—that which accompanies mitral regurgitation is usually loud, strong, and blowing; that which accompanies aortic regurgitation is usually soft and whispering, because the force with which the blood is propelled from the ventricle is much greater than that with which it enters it."

SCIENTIFIC ARTICLES.

ON THE ACTIVE PRINCIPLE OF THE CALABAR BEAN.

The active properties possessed by the *Physostigma Venenosum*, or Calabar bean, have led chemists to suppose that these seeds owed their characters to the presence of an alkaloïd even more powerful than strychnia; and in fact, MM. Jobst and Hesse, of Stuttgard, have discovered an alkaloïd which they call *physostigmine*. According to their researches, the active principle of the seeds resides only in the cotyledons. They obtained it by treating the beans with alcohol, and then taking up with ether the residue remaining after the evaporation of the alcoholic solution. The ethereal solution, afterwards evaporated, left pure *physostigmine*, or as some have proposed to call it, *Kalabarine*. The alkaloïd appears as an amorphous brownish-yellow mass, and is at first separated under the form of oily drops. It is readily soluble in ammonia, caustic and carbonated soda, ether, benzine and alcohol, but less soluble in cold water. It is entirely precipitated from its ethereal solution by animal charcoal. The aqueous solution has a slightly burning taste, a decided alkaline reaction, and gives an abundant reddish-brown precipitate with iodide of potassium, and a precipitate of hydrated oxide of iron with a solution of chloride of iron; and fused with hydrate of potash, it disengages vapours which have a strongly alkaline reaction. Acids dissolve it easily, giving rise to solutions of salts which generally present a dark red colour, and more rarely a dark blue. The hydrochlorate of physostigmine gives whitish-red precipitates with tannin; pale yellow with chloride of platinum; bluish with chloride of gold, the metal being reduced; and reddish-white with bichloride of mercury. Twenty-one beans yielded only a small quantity of alkaloïd.

Two drops of a watery solution of the alkaloïd, placed upon the eye, caused contraction of the pupil, at the end of ten minutes, to about a twentieth of its primitive diameter; the pupil remained in this state about an hour, and at the end of from four to six hours it resumed its original dimensions. Taken internally, physostigmine is as poisonous as the most dangerous cyanides. A quantity of the alkaloïd corresponding to one bean having been administered to a rabbit, at the end of five minutes the animal fell down, remained motionless, and died twenty-five minutes afterwards, or about half an hour after having swallowed the poison.

Physostigmine causes contraction of the pupil even in the eye of an animal which has been dead for some time. Two drops of the watery solution having been placed upon the eye of a rabbit an hour after it had been killed by mechanical means, it was ascertained that the pupil was contracted by one quarter as compared with the opposite eye. A rabbit killed by physostigmine did not present this phenomenon; but it was ascertained to occur in a slight degree in another animal poisoned by cyanide of potassium. Hence it appears that the muscles, even after death, are still susceptible of being influenced specifically, not only by the galvanic current, but also by physostigmine.—Dr. SEMPLE'S 'Report on Materia Medica and Therapeutics,' in the 'Brit. and Foreign Medico-Chirurgical Review.'

IODINE AS A DISINFECTANT.

A paragraph has been going the round of the public journals, having reference to Dr. Richardson's paper, read at the Newcastle Meeting of the British Association for the Advancement of Science. This has led to various inquiries as to the mode in which iodine should be used. The following facts may therefore be useful:—

1. Iodine is a metalloid, resembling much the scales of iron that fall from the blacksmith's anvil. It may be bought at the price of eightpence an ounce.

2. It is soluble in spirit, and may be used as a solution in spirit, in which case rags are dipped into the solution, and suspended in the room requiring to be disinfected. But the most simple way is to use it in the solid form, or in extreme cases in the form of vapour. Used in the solid form it is simply necessary to place one drachm, or the eighth part of an ounce, of iodine in a cup, glass vessel, or common chip box, and covering the vessel over with a piece of gauze or muslin, to place it on the mantelshelf of a room. Or a little iodine may be placed in a china or glass ornament on the mantelshelf. In time the iodine thus placed becomes diffused throughout the air of the apartment, which it thoroughly disinfects if any organic matter be present. When rapid disinfection is called for, the iodine may be placed on a porcelain or a common plate or saucer, and the heat of a candle may be applied underneath. The iodine is thus driven off in a violet-coloured vapour, which quickly diffuses through the air of the room, and immediately destroys all the organic products which are the cause of the disagreeable odours.

3. Iodine acts in the same manner as do chlorine, bromine, and active oxygen or ozone. It is nearly as powerful as chlorine, and when diffused by means of heat quite as powerful. It is much more readily applied than any other disinfectant, and does not seem to be deleterious, as chlorine is to animal life. It also appears to produce no deleterious effects on gilded and metal surfaces. Indeed, it may be placed in the solid form, in the way described, in every room in a house.

4. Iodine must not be understood at any time as replacing ventilation, for it has no chemical influence on the product of breathing known as carbonic acid, and it would be a mistake to suppose that because it destroys the bad smell of a close apartment, it prevents the necessity of opening the windows. But combined with good ventilation, it destroys organic impurities, and gives a freshness to the air of a house, like that which is experienced in the air passing over the sea. Indeed, it has been assumed that in sea air iodine is present, and that the value of sea air depends on this circumstance.

5. Iodine may be used successfully for another purpose, viz.: in cases where the breath is very fœtid. The metalloid may be placed in a common smelling bottle, and may be occasionally inhaled to such an extent as not to produce dryness or soreness of the nostrils or throat. We have known it thus applied with great and immediate advantage, and have found it destroy almost at once the disagreeable odours arising from the eating of onions and from smoking tobacco. We have also recently used it, on the suggestion of Dr. Wynn Williams, as an application to fœtid and indolent ulcers and sores on the human body. In hospitals, at the instance of Mr. Hoffman, of Margate, it is now employed in the beds of the sick in some cases, as where there are extensive bed sores. In these cases, the chip box is employed; the box containing the iodine, and covered with muslin, being placed under the bed-clothes. To this process there is one objection,—the sheeting becomes tinged of a brownish colour; the discolouration is easily removed, however, by washing the sheets with a little soda. In a word, iodine may be considered as the readiest and the best of all disinfectants; and as its supply is unlimited, we may expect to see it taking an important commercial position as a disinfecting agent.

Messrs. Garden and Robbins, chemists, of Oxford street, have recently undertaken to supply all the necessary and simple apparatus for the purposes named above.—'Social Science Review.'

ON THE CHEMICAL, PHYSIOLOGICAL, AND THERAPEUTICAL PROPERTIES OF IODOFORM.

Dr. Righini's researches in relation to iodoform have shown that this substance is superior to the other preparations of iodine, in possessing anæsthetic as well as antiseptic and antimiasmatic properties. Morétin and Humbert, as well as A. Maitre, have proved that iodoform may, in consequence of the large proportion of iodine which it contains, be substituted for the other preparations of iodine, as well as for iodine itself, in all the cases where this medicine is indicated; and they have also shown that the therapeutical application of iodoform possesses the advantage over the other preparations of iodine in not causing either the local irritation or the other unfavourable symptoms

which sometimes necessitate the discontinuance of this drug. Iodoform, in its chemical relations, resembles chloroform, being a teriodide of formyle, and it is prepared by the mutual action upon one another of iodine, alcohol, carbonate of soda, and water. It forms bright yellow, friable, soft scales of a slightly pungent taste, and having a smell of garlic. It evaporates in the air in small quantities at a low temperature, and sublimes at a higher one; and at 120° the vapour is decomposed into carbon, hydriodic acid, and iodine. It is very slightly soluble in water, but is easily dissolved in alcohol and ethereal oil.

A series of experiments was instituted to ascertain the presence of iodine with animal fluids and the excretions of persons who had been treated with iodoform. It was found in the blood of a woman who had been successfully treated for a swelling of the thyroid gland, followed by acute inflammation, and in the saliva and the sweat of several persons who had taken iodoform. It was discovered in the milk of nurses who had had iodoform administered for the purpose of acting therapeutically upon their scrofulous and rachitic nurslings. It was also found in the tears, the mucus of the nose, the menstrual blood, and in the urine, and even in the bile, the fæces, and the liquor amnii. By the administration of iodoform internally, an increase of the secretions of the liver and pancreas was observed, and still more of the secretions of the salivary glands and the kidneys. Emaciation was never observed, but, on the contrary, a slight increase of the deposition of fat. The tongue and œsophagus were not irritated by iodoform, and the mammary glands were not made sensitive and painful, as in the employment of iodide of potassium or iodine itself.

Iodoform may be given without danger in doses amounting to three grammes daily, but after very large doses Maitre observed appearances of iodism. In the lower animals it is poisonous in large doses. When employed internally, iodoform combines partly with the proteinaceous substances to form soluble albuminates, which are easily absorbed, and partly with starch, if the latter is used with food, to form iodide of starch, under the influence of the gastric juice, and probably to be expelled undigested with the fæces.

A long list of diseases is given in which iodoform is said to have been administered with advantage, as tubercle, scrofula, disorders of menstruation, tumours, stoppage of the secretions in the uterus and the breasts, impotence, ozæna, ophthalmic blennorrhœa, obstinate exanthems, periostitis, tuberculous affections of the skin and mucous membranes, deep ulcerations, &c. It is also stated that iodoform in solution in alcohol is used with advantage externally in chronic neuralgia, lumbago, and rheumatism. Suppositories are recommended containing oil of cacao and iodoform. Iodoform cigarettes, made of belladonna leaves and iodoform, are also described, together with liniments, salves, and gargles, in which this substance forms a constituent.—Dr. SEMPLE'S 'Report on Materia Medica and Therapeutics,' in the 'British and Foreign Medico-Chirurgical Review.'

HOSPITAL REPORTS.

KING'S COLLEGE.

CASE OF DISEASE OF THE FEMUR.

(UNDER THE CARE OF MR. HENRY SMITH.)

G. C., æt. nineteen, was admitted on 21st January, suffering from disease of the right femur.

History.—He states that four years ago, whilst working as an engine-cleaner, his right leg was caught by some portion of the machinery, the result being a wound in the inner part of the thigh, and at the upper part of the front of the leg. He was an in-patient at St. Thomas's Hospital for eight months, and went subsequently to Margate for seven months. The leg recovered itself perfectly, and occasioned him no inconvenience until about six weeks since, when one morning a stiffness suddenly came on, which increased towards night, and was attended with so much pain that he was obliged to lie up from it. The treatment adopted upon this occasion consisted of poultices applied to the whole of the inner part of the thigh; a large abscess pointed and burst on the fourth day from that on which he felt the stiffness and the pain; there has been a copious discharge of pus ever since, but the leg has not been painful.

On the 18th of January, an ulcer broke out just above the original opening, which was healing; the discharge escapes chiefly from the more recent aperture, which is now about the size of a shilling.

Jan. 31st.—Left the Hospital this morning. There is still a healthy ulcer, and it is healing up rapidly. The sinus has closed up altogether.

CASE OF SEBACEOUS TUMOUR.

E. D., æt. twenty-four; married; was admitted on Jan. 23rd as a patient, from a sebaceous tumour the size of a small walnut, and situated on the left cheek. She first noticed it twelve years ago, and since that time it has been growing gradually, sometimes, however, decreasing in size for a short interval and then again increasing.

Jan. 24th.—To-day it was removed by Mr. Smith.

Feb. 7th.—No bad symptoms having arisen since the operation, the patient was to-day dismissed, cured.

REMARKS ON DISEASES OF THE FEMUR.

Under the head of "Diseases of the Femur," we would include that form of morbus coxæ which originates in the head of the thigh-bone. The affection, though not altogether peculiar to children of a strumous diathesis, is yet most frequently met with in such subjects.

The disease commences in the head of the femur, and in many instances is in the beginning attended with little else than a feeling of stiffness or fulness in the joint; this sensation is succeeded by the acute pain which characterises the disease. The affection consists in a deposition of true tuberculous matter into the cancellous structure of the head and neck of the bone; this tuberculous deposit is of a soft and friable nature, and of a yellowish colour, and is analogous to the cheese-like deposit which occurs in various organs involved in strumous disease.

The symptoms are not at all well marked, and increase or become aggravated by very slow degrees; they are not of the acute character, assuming rather the subacute form. They will be generally found to be as follow:—The child is observed to walk and run in an unaccustomed manner; the gait, instead of being natural, becomes unsteady and shuffling; the child limps rather than walks; the knee is somewhat bent; the foot is not laid upon the ground, but the entire weight of the body rests upon the opposite foot and leg, or is supported partly by these and partly by the toes of the unsound limb. In walking, the child will be noticed to trip frequently, as though the floor or carpet were uneven; and when it runs, the limb of the affected side is raised from the ground, and the little patient hops, instead of using both the legs.

The unsound limb itself is apparently—but not really—shorter than that of the opposite side; there is eversion, abduction, and a flexing of the leg upon the thigh, so that the knee is slightly bent.

The apparent shortening of which we have just spoken is dependent upon, not any organic or actual structural change in the femur, in the pelvis, or in the soft tissues by which they are surrounded, but on the raising of the foot from the ground and the consequent elevation of the entire limb, in which elevation the pelvis participates and will on inspection be found to be placed obliquely; its anterior superior spine being turned forwards and placed on a level higher than the same process holds on the opposite side.

The spinal column will also be found to deviate from its normal curvatures; but this condition exists not from any actual disease, but merely from the elevation of the foot.

The shortening takes place early in the disease. It can easily be ascertained to be an apparent and not a real shortening; this is best done by taking the measure of the limb from the anterior superior spine to the knee-joint, or rather to the outermost edge of the patella; and, again,

from this point to the malleolus. Moreover, the obliquity of the pelvis is readily to be detected by placing the child on its back in bed, and then instituting an examination; and by keeping the child confined to bed this apparent shortening gradually passes off and is succeeded by an apparent lengthening, the cause of which is a lowering of the pelvis on the diseased side.

The knee-joint of the unsound limb is, in many instances, swollen and puffy, and the patient is often found rubbing it, as though all the disease were situated in it; it may, in fact, be so altered from its natural condition, and may be the seat of so much uneasiness and positive pain, that the surgeon, unless he be upon his guard and make a very careful examination, may easily fall into error, and, making a wrong diagnosis, may pronounce a wrong opinion as to the ailment of the child.

These are the objective symptoms; and the subjective will now be passed in review, and be brought under our consideration. They are:—A constant and dull aching pain in the region of the hip-joint; this may or may not have been preceded by a somewhat acute, stinging, darting pain in the same region. The pain, of what character soever it may be—but especially in the more advanced stages of the disease—is always increased by rotation of the limb, by abduction, by percussion on the heel or on the trochanter, or by deep pressure in front of the joint over the pectinæus muscle; it is also aggravated by walking, or even by any use of the limb, be it ever so gentle. There is likewise pain experienced in the inside of the knee-joint; and there is also some tenderness, owing to exalted cutaneous sensibility. This pain and this tenderness are communicated from the hip-joint through the medium of the articular branch of the obturator nerve, which, becoming engaged in the morbid action, sends to the knee, by means of a long descending branch, the peculiar pain, indicative of such morbid action, and of the implication of the trunk of the nerve in the same.

In making our examination of the spine, we cannot fail to notice that the buttock of the affected side is flattened, its natural fold obliterated, and that it is flabby to the touch, and is seemingly wider than before the disease invaded the joint, and that its natural fulness is lost. In the female the vulva of the unsound side hangs lower than it does on the unaffected side.

The disease progresses; abscesses form; the health becomes evidently impaired; the matter determines to the outer or inner side, to the back or front, of the joint: if to the back, it insinuates itself under or between the glutei muscles, and, after burrowing between these, points in the integument of the buttock; if, however, the pus determine anteriorly, it gets under the pectinæus, and causes excessive pain to the patient from the compressive force it exercises upon the obturator nerve. This pain is chiefly experienced down along the inner aspect of the thigh.

The limb now becomes really shortened; and this is due to degeneration and atrophy of the entire limb, or to an increase in the disorganisation of the bone, the processes of absorption and disintegration becoming the more complete as the disease continues; or to a dislocation of the head of the bone upon the dorsum ilii, or to a combination of all these conditions. At this time also, besides the shortening, there is an alteration in the position of the limb, the foot and thigh being inverted and adducted.

This alteration is occasioned by the fatty degeneration and subsequent absorption of the external rotators and abductors, as well as by the formation of collections of matter, which, acting as a stimulus to the muscles in the vicinage of which it lies, alters their normal action, and brings them into more powerful play; again, the adductor muscles, having lost all counterbalancing power, act unopposed, and so draw the limb upwards, at the same time that it is turned inwards and forwards. Unless active measures be adopted for the treatment of the diseased conditions, the health quickly succumbs beneath the combined lowering influences of hectic fever and discharges from the abscesses.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XX.

Leaving Calomelas to be noticed with the other mercurial salts and compounds, we come next to

CALX CHLORATA, the new name for Calx Chlorinata of former Pharmacopœias, and the Chloride of Lime of commerce. No directions for the preparation of this compound are given in the British Pharmacopœia, which seems strange, when we see the book to contain elaborate directions for slaking lime. Chloride of lime, however, as everybody knows, is made in this country in enormous quantities, by exposing freshly-slaked lime to an atmosphere of chlorine. When this is done, several reactions take place. Some of the lime parts with its oxygen, which unites with some chlorine to form hypochlorous acid, which again immediately combines with lime to form hypochlorite of lime, the deoxidized calcium uniting with chlorine to form chloride of calcium—

$$2\,(Ca\,O,\,H\,O) + 2\,Cl = Ca\,Cl + Ca\,O,\,Cl\,O + 2\,H\,O.$$

The lime must always be in excess; and thus, as the Pharmacopœia states, calx chlorata is a mixture of "hypochlorite of lime, chloride of calcium, and a variable amount of hydrate of lime." The value of chloride of lime, both as a medicinal and a bleaching agent, depends upon the amount of *available* chlorine it contains, which is, of course, only that present in the form of hypochlorous acid. This is ascertained indirectly by determining the amount of iodine which a known weight of the bleaching powder will set free from iodide of potassium. Ten grains of the powder, the Pharmacopœia says, when mixed with thirty grains of iodide of potassium dissolved in four ounces of water and acidulated with two drachms of hydrochloric acid, gives a red solution, which should require at least 85 measures of the volumetric solution of hyposulphite of soda to discharge the colour. This will indicate at least 30 per cent. of available chlorine in the sample, which is about the average amount in fresh well-made specimens of the compound.

The chemical changes which take place in performing the above test are as follows:—The chlorine liberated by hydrochloric acid sets free an equivalent amount of iodine from the iodide of potassium, and when hyposulphite of soda is added to a solution of iodine in iodide of potassium, iodide of sodium and tetrathionate of soda are formed—

$$2\,(Na\,O,\,S_2\,O_2) + I = Na\,I + Na_2O,\,S_4\,O_5.$$

LIQUOR CALCIS CHLORATÆ.—From what has gone before, it will be seen that this preparation is a solution of hypochlorite of lime, chloride of calcium, and a small amount of lime in water. The fluid ounce will contain about 44 grains of the chlorinated lime, and to answer the Pharmacopœia test should yield 13 grains of available chlorine.

LIQUOR CHLORI.—This is simply a saturated solution of chlorine in water, which, at ordinary temperatures, will retain twice its volume of the gas. It constitutes a yellowish green liquid which smells very strongly of chlorine.

The solution is made by passing slowly a current of chlorine through the water. The chlorine is to be obtained by gently heating in a flask binoxide of manganese with hydrochloric acid, when the following changes take place:

$$Mn\,O_2 + 2H\,Cl = Mn\,Cl + 2\,HO + Cl.$$

One fluid ounce of the solution, to which 20 grains of iodide of potassium have been added, should require 75 measures of the solution of hyposulphite of soda for its decolorization, which will indicate the presence of about 26 grains of chlorine.

CHLOROFORMUM.—Chloroform, we may state briefly, is obtained by distilling a mixture of water, rectified spirit,

slaked lime, and chlorinated lime. When these are heated together, some complex changes take place. In the first of these it is supposed that chloral (C_4 H Cl_3 O_2) is produced, and this, on coming in contact with hydrate of lime, produces chloroform and formic acid, the latter combining with the lime :—

$$\underbrace{C_4 H Cl_3 O_2}_{\text{Chloral.}} + Ca O, HO = \underbrace{C_2 H Cl_3}_{\text{Chloroform.}} + \underbrace{Ca O, C_2 HO_3}_{\text{Formiate of lime.}}.$$

Other changes, however, take place as well, which result in the production of some heavy volatile oils which are removed from the crude chloroform by treating it with sulphuric acid.

We need not go further into the chemistry of the formation of this important medicine, but proceed to what are of more importance to the practitioner—its characters and the tests for its purity.

It is a limpid colourless liquid, of an agreeable ethereal odour and sweet taste. The Pharmacopœia adds that it mixes with ether and alcohol in all proportions, but this is not quite correct. Mr. Squire gives the following list of solubilities :—"In rectified spirit, 10 in 6 ; in ether, 10 in 70 ; in water, 10 in 2,000 ; freely in olive oil and spirit of turpentine. Does not dissolve in glycerine."

The impurities in chloroform arise from two sources, carelessness in the manufacture and fraud. In the first case, chloroform may be supplied which has never been submitted to purification, or has been but imperfectly purified. This may contain alcohol and empyreumatic oils, which latter will be more abundant when the chloroform has been prepared from methylated spirit. They will be detected by sulphuric acid, which becomes coloured when agitated with chloroform containing them. They will also leave an unpleasant odour when chloroform contaminated with them is evaporated.

Alcohol, which may also be a fraudulent addition, will be detected by adding to the suspected chloroform a small quantity of sulphuric acid and a fragment of bichromate of potash, whereby a green colour will be produced by the reduction of the chromic acid. An easier method of discovering the presence of alcohol is by dropping a little chloroform into water. If it is pure, the chloroform remains clear ; but if alcohol is present, the surface of the globules becomes opalescent. Potassium, which the Pharmacopœia gives as a test, will reveal the presence of alcohol and any other oxygen compound by causing the evolution of hydrogen and the coloration of the liquid.

In all cases, however, the specific gravity will be a tolerably accurate test of purity. The Pharmacopœia puts it at 1·496 at 60° Fahr. ; and we need only state that it should never be below 1·490, nor above the Pharmacopœia standard.

It is only necessary to add that the vapour of chloroform should never be administered without first ascertaining, by means of test paper, that it gives no acid reaction. Under some circumstances, not well understood, chloroform undergoes spotaneous decomposition, resulting in the liberation of hydrochloric and other chlorine acids, which have produced seriously prejudicial effects on the patient.

REVIEW OF BOOKS.

Transactions of the Obstetrical Society of London. Vol. V., for the Year 1863. With a List of Officers, Fellows, &c. Pp. 325. London : Longman and Co. 1864.

The present volume of the 'Transactions' of the Obstetrical Society is in every respect equal to its predecessors in the generally interesting nature of its contents, and in the record of cases of special importance or rarity. We are happy to find that the condition of the Society itself is very prosperous, that its meetings are numerously attended, that its finances are flourishing, that its sphere of operations is extending, and that its list of fellows and contributors comprehends practitioners in all parts of the world. It appears that the library of the Society is rapidly increasing in extent, by the donations of the members, among whom Sir Charles Locock and Dr. Clay have been lately the most conspicuous benefactors, and that it is now desirable to find a place for the reception of the books and a librarian to take care of them. In the annual address of the President it is mentioned that the object of the Society is not to rival existing general medical libraries in the richness and extent of the collection, but to form a library of purely obstetrical works, which would be specially available for those who are engaged in the practice of midwifery.

Among the general subjects, that of ovariotomy occupies, as may be expected, a prominent position ; and Dr. Clay contributes an interesting paper containing the results of his experience in this operation, together with a very interesting case in which the uterus and its appendages were entirely removed with complete success ; and a second case of the same kind is alluded to in which the result might have been equally successful but for an unfortunate accident which happened to the patient as she was recovering. The employment of chloroform and other anæsthetics in midwifery practice forms the subject of an important discussion following a paper by Dr. Kidd, the general feeling appearing to be that the use of these agents was justifiable, and that it was not followed by any untoward results. It was not maintained that they should be always employed, but they were considered to be very valuable in difficult cases, and in puerperal convulsions they were found generally useful in quieting the system. Dr. Skinner, of Liverpool, recommends in one of the papers the employment of Faradisation, or the local application of the galvanic current as a galactagogue, and relates eight cases in which this plan was employed with success. Dr. Clay describes some cheap and simple appliances, in the form of wire-loops, horse-shoe wires, &c., for correcting anteversion, retroversion, obliquities, and prolapse of the unimpregnated uterus, the paper calling forth a variety of remarks upon mechanical uterine supports in general, Dr. Oldham expressing his disbelief in their efficacy altogether.

Among the cases of special interest are some very rare and curious instances of abnormal conditions of the generative apparatus in women ; in one there was a double pregnancy, one uterine, and the other extra-uterine or fimbrial, both advancing simultaneously to the full period of gestation, the result being fatal, one child having been born during the woman's life, the other being found after death in the peritoneal cavity. Other cases are recorded of tubal gestation, and extra-uterine fœtation, in which the real nature of the abnormity was revealed after death ; and a case of Cæsarean section is described, in which the usual result of the death of the mother supervened, but the infant survived.

We must not omit to notice that the volume is very well got up, and the illustrations are numerous and admirably executed.

On Combined External and Internal Version. By J. Braxton Hicks, M.D., F.R.S., one of the Lecturers on Midwifery and Diseases of Women at Guy's Hospital, &c. Pp. 72. London : Longman and Co. 1864.

The subject of this memoir was originally brought forward in the pages of a contemporary some years ago, and again before the Obstetrical Society during the past year, when the plan proposed by the author was received with favour by the members present. Since that time a considerable part has been re-written, new illustrative cases added, and the whole matter brought up to the present time. Those who are unacquainted with the practice now proposed by Dr. Hicks may be informed that it is an improvement upon the old method of turning in preternatural labours, and that its novelty consists in the use of both of the practitioner's hands, one within the uterus and the other outside the abdominal walls, by which means the fœtus is turned into a position convenient for delivery. The merit of originating this plan is due to a German physician named Wigand, who published an essay in 1807, recommending the practice alluded to. The title of the essay is, 'Von einigen ausseren Handgriffen, wodurch man, unter der Geburt, die regelwidrigen Lagen der Frucht verbessern Kann' ('Of some External Manipulations, by which, during Childbirth, the Preternatural Position of the Fœtus may be

rectified'); but great merit is due to Dr. Braxton Hicks for the able manner in which he has carried out the plan proposed, and has explained its applicability in certain cases. It is not maintained that this method is intended to supersede the necessity of turning in preternatural labours, but it is argued that there are certain instances in which it is safe and efficacious; and Dr. Hicks gives a very good summary of the reasons which justify its adoption in special cases.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Professor FERGUSSON continues his "Lectures on the Progress of Anatomy and Surgery during the Present Century," and an abstract of the present discourse we give in another place.——Mr. BAKER BROWN continues his "Lectures on Some Diseases of Women remediable by Operation," his present lecture being on uterine hæmorrhage, and the treatment consisting in incising the mouth and neck of the uterus. Several cases are described, in which this treatment was successful; but in one there was recurrent fibroid tumour which was removed by a series of operations, and perchloride of iron was subsequently employed locally as an astringent.——Mr. MCWHINNIE contributes "Some Observations on Certain Tumours of the Neck, with Notes relating to its Surgical Anatomy." He shows the danger of making an incision low down in the neck for the relief of various urgent symptoms, and relates a case in which a medical man, in his desire to restore life by admitting air into the lungs of a person who had been some time immersed in water, plunged a penknife into the trachea. As it happened, the patient was quite dead, but, on inspection of the body, it was found that the blade of the knife had entered the left brachio-cephalic vein. In another case, a scalpel was thrust through the middle of the neck into the trachea, to relieve urgent dyspnœa supposed to arise from some obstruction in the larynx; great bleeding followed and death very soon ensued. It was found, on examination, that the isthmus of the thyroid body had been cut, and the trachea was filled with blood; but the original cause of disease was ascertained to be a large aneurism of the aorta, pressing upon the bronchi. As a general rule, Mr. McWhinnie recommends the incision to be made high up in the neck, when it is desirable to open the trachea, and after laying bare the cricoid cartilage, to cut immediately below this cartilage, and to cut some of the upper rings of the trachea. This operation is necessary in several urgent cases of disease; but Mr. McWhinnie does not speak very highly of tracheotomy in croup.

THE 'MEDICAL TIMES AND GAZETTE.'

We now give an abstract of the fifth lecture of Professor FERGUSSON, "On the Progress of Surgery during the Present Century," as reported in the present number of the 'Medical Times and Gazette.' The lecture begins with a review of those operative measures which constitute Conservative Surgery. Another and a just meed of praise is bestowed upon Mr. Syme for his having laboured, and that, too, successfully, for bringing in and establishing as legitimate operations excision of the elbow-joint and removal of the head of the humerus. To the strenuous exertions of Mr. Hancock in the field of Preservative Surgery, reference is likewise made; and his name is brought forward especially in connection with excision of the ankle and hip joints. The rest of the lecture is professedly devoted to the interesting subject of excision of the knee-joint. The striking differences in the lower from the upper extremities, both as regards their use and their conformation, and also their difference in man when compared with the hinder extremities of other animals, are pointed out. The advantages gained by amputation of a limb in cases where hectic was running the patient to a rapid end are touched upon, not, however, for the purpose of dilating upon them, but rather to show more plainly the superiority of the excision to the amputation. In the review of the history of excisions, the name of Parke, the originator of such operations, stands, as of course it should, at the head of the list, and is succeeded by that of the elder Moreau, who, in the year 1797, performed the excision of the elbow-joint which had been proposed by Parke fifteen years previously. In the year 1792, Filkin, of Northwich, successfully excised the knee. The name of Justamond is mentioned in reference to partial excision of the elbow. The efforts of Parke and Moreau were renewed by Hewson, Crampton, and Syme; but while excision of the elbow became established in Surgery, extirpation of the knee fell into disrepute, till it was revived by Mr. Fergusson in 1850, and by Jones, of Jersey, about the same time. Professor Fergusson's first case died of acute necrosis of the femur; Mr. Jones's were more successful, only one out of fifteen being attended with fatal results. Excision of either of these joints is a formidable undertaking, but that of the elbow is especially the coarser, though the same operation on the knee looks to the novice of far greater magnitude. The incomparable benefits to be derived from excision of the knee in cases of diseases of that joint, instead of performing the old operation of amputating the thigh, are made particularly to engage attention. The operation has been more frequently performed in the smaller cities and in provincial towns than in London, and, upon the whole, has been so seldom performed, that at this moment it is not an easy matter to decide for or against the operation. Mr. Jones had large experience in this surgical procedure, and next to him Dr. Humphry, of Cambridge; the rate of mortality in the cases of the former was one in fifteen, that in those of the latter was one in thirteen; but Professor Fergusson has operated upon forty patients, and out of that number has lost fifteen. This rather high death-rate is attributed to the situation of the King's College Hospital, and does not make Mr. Fergusson deem this surgical measure as at all inferior to amputation of the thigh. Statistics collected by Mr. Price show excision to be nearly as fatal as amputation. An objection urged against excisions is the length of time required to effect a cure, the curative process in the case of amputations being said to be limited to a period of about six weeks. But these are erro

neous data upon which to build, inasmuch as the after conditions of the stump are not taken into consideration; besides, account should be taken of the size of the knee-joint, and of the constant and onerous duties the lower extremity is called upon to fulfil. Admittedly, wounds made for excisions are very tedious in healing; but yet patients, aided by crutches, may walk about, and even put the foot to the ground, after an expiration of—in some instances—only three weeks from the date of operation. This triumph cannot be claimed for cases in which compound fracture of the tibia has occurred.——Dr. DAY mentions, under the head of "Original Communications," a case in which moveable kidney simulated pregnancy; and Dr. MCCRAITH continues his paper on "Lithotomy in Smyrna," and gives a list of the appliances he uses in the operation, and his method of performance; also a description of some of the calculi he has removed, and, in a tabulated form, the age of the patient, his general appearance, the result of the operation, the weight, shape, and dimensions of the stone.

PARISIAN MEDICAL NEWS.

MECHANISM OF THE CIRCULATION IN THE HEART.

The theory of the mechanism of the cardiac circulation has been simultaneously brought forward by M. Hiffelsheim at the Academy of Sciences, and at the Academy of Medicine by MM. Béclard and Gavarret, who reported on the researches instituted by MM. Marey and Chauveau. M. Hiffelsheim denounces as dangerous too strict an application of the laws of dynamics and natural philosophy, in the interpretation of physiological facts, but he endeavoured, at the same time, perhaps with more talent than success, to establish, on data supplied by the exact sciences, the correctness and originality of his theory of recoil. The discussion at the Academy of Medicine was spirited and interesting, and the experimental inquiries of MM. Marey and Chauveau, which confirm the theory generally adopted of the mechanism of circulation in the heart, met with no contradiction except from M. Beau, an earnest and sincere adversary, and at the same time a thoroughly skilled debater. In vain did MM. Bouillaud, Béclard, and Gavarret put forth all their power of argument to annihilate the doctrine upheld by their learned colleague; M. Beau unflinchingly defended his position, and professed himself ready to suffer martyrdom, sooner than acknowledge that the impulse of the heart is the result not of systole, but of ventricular diastole.

We cannot refrain from observing that M. Beau's opponents ascribe to the auricle too insignificant a part in the action of the heart; and in a speech that attracted less notice than that delivered by M. Gavarret, M. Parchappe appears to us to have argued more soundly, in showing, with Harvey and Haller, the real share of that portion of the viscus in the complex mechanism of its circulation.

THE ORIGIN OF MAN.

Several communications more or less relative to Anthropology have been forwarded to the Academy of Sciences, amongst which was a paper by M. Trémeaux, "On the Transformations of the Human Race." M. Trémeaux is a traveller who has visited every part of the globe, and who adduces the results of his observation and experience in support of the doctrine of the specific unity of the genus Man. He contends that the differences of structure and colour are merely secondary changes, effected by time and climate. With regard to colour the assertion is not a new one; and it is a generally-received fact that white men become darker, and negroes bleach, when they respectively migrate to torrid or temperate latitudes, and that the changes become further confirmed in a few generations. But M. Trémeaux does not attempt to offer the same explanation of the enormous differences observed in the shape of the skull and the degree of intellectual development. Indeed, it is obvious that the shape of the head and the colour of the skin cannot possibly be influenced by the same cause; and the author remarks that "some very dark tribes are found to possess regular features, whereas in others deformed features are allied with clearer complexions." But in man the colour of the skin is a secondary matter. The various physical types, expressive of mental development, are of far greater importance. To solve the problem, M. Trémeaux calls in another element—viz., the influence of the age of the soil on the inhabitants. In his opinion, the lowest types are to be met with in primary soils, and, conversely, the most perfect types coincide with the geological improvements of the different regions of the surface of the globe. Hence, the author concludes that the development of the human form has advanced with the migration of the original races to lands of recent formation.

"The Indo-European race, for instance, does not differ except when much difference exists in the nature of the soil. The race is handsome in Southern and Western Europe, in Georgia, Circassia, and Persia, where the more recent changes of the soil are observed.

"In the far East, we find the finest Mongolian type in the neighbourhood of Pekin, where the strata are recent, and the most deformed in the primary regions from which flows the Yeniseï.

"We may, in addition, notice even in France, despite the division of land, well-marked differences of type; and although the lower orders emigrate from the primary uplands of Limousin, Auvergne, and Savoy, and, like the gipsy race, periodically wander to more favoured tracts of country, where improvement of type is favoured by crossings, the local influences are still observable."

In its notice of this communication, the 'Courier de Saône et Loire' adopts the same view, and remarks, "It is impossible not to be struck by the differences between two adjacent districts, and to avoid noting the dissimilarity of the Morvan husbandman and the vine-growers of Mercurey, or the inhabitant of the banks of the Saône. The soil around Châlons is of far more recent formation than the table-lands of Morvan (Nièvre), hence a handsomer race of men, and greater aptitude to civilisation in the plains, than in the district of Autun."—'Journal of Practical Medicine and Surgery.'

SANITARY STATE OF LIVERPOOL.—A deputation from the Local Health Committee has had interviews with the Registrar-General as to the desire of the committee to trace the causes of the high bills of mortality of the borough; and the Registrar-General has promised to cause an abstract of the census returns of 1861, showing the number of families, and the number of persons in each family recorded as residing in every house in the borough, to be prepared at the cost of the corporation. Fifty pounds is mentioned as the probable cost.

SCARLET FEVER RIOT AT TUNBRIDGE WELLS.—On Saturday night last a riot of curious origin took place at Tunbridge Wells. A few weeks ago it was rumoured that an epidemic in the shape of typhus and scarlet fever had visited the place, and as a consequence a large number of visitors left. The report appears to have given the lodging-house keepers great annoyance, and as a Mr. Webber was identified with it, a large mob of about 1,000 persons assembled in front of his house on the evening in question, and having burnt him in effigy, commenced to smash his plate-plass windows. The small police force was quite powerless, and the crowd was only dispersed at a late hour by a heavy fall of rain. On Sunday the excitement in the town continued, and another riot was expected. It is said that the sanitary inspector sent down by Sir G. Grey, on Mr. Webber's application, could find nothing to justify the reports respecting the unhealthy condition of the town.

THE MEDICAL CIRCULAR.

WEDNESDAY, JULY 13, 1864.

THE RECENT ELECTION AT THE COLLEGE OF SURGEONS.

The annual meeting of Fellows of the Royal College of Surgeons of England has resulted in the election of Mr. Le Gros Clark, Mr. Hancock, and Mr. Curling, as the new members of the Council. As we have before mentioned, there were six candidates—Messrs. Hancock, Gulliver, Turner, Curling, McWhinnie, and Le Gros Clark, and the number of votes recorded for each candidate was as follows:—Mr. Le Gros Clark, 148; Mr. Hancock, 138; Mr. Curling, 134; Mr. Gulliver, 106; Mr. Turner, 97; and Mr. McWhinnie, 62.

The result will, we believe, astonish no one, and will disappoint no one. The gentlemen elected are all of high professional merit, and each fully deserves the honour of a place at the Council Board. Mr. Hancock was elected only last year, and his retirement on the present occasion was a mere formality, rendered necessary by an absurd law that a Councillor elected in the place of another who retires before his full period of service, can serve only for the time left unexpired by his predecessor. It was, therefore, universally believed that Mr. Hancock would be re-elected to fulfil his due period of office. Mr. Curling, last year, was a candidate for election, but was rather low on the list, in consequence of some coquetting on his part; but his claims to be made a Councillor were universally acknowledged, and on the present occasion they have met with a successful response at the hands of the Fellows.

The real contest was for the third appointment, and it was difficult beforehand to prognosticate with anything like certainty as to the chances of the other candidates. If the feeling of the Fellows was decidedly in favour of eliminating from office the retiring, but eligible candidates, Mr. Le Gros Clark would of course receive very general support as a new man in the Council, though a well-known and highly esteemed surgeon, and a Lecturer and Medical Officer at one of our largest hospitals. If, on the other hand, it was thought that gentlemen who had served with distinction in the Council were not necessarily, *ipso facto*, ineligible to serve again, then there could be no question that Mr. Gulliver had a very strong chance of success, and that one of the other candidates could wait for another year.

A very important principle was involved in the candidature of Mr. Turner, of Manchester, for it was felt that the Council of the College ought to represent, at least in part, the provincial surgeons; and as Mr. Turner was willing to serve, it was felt that no better or more deserving candidate could be proposed than that excellent and distinguished gentleman. If the provincial Fellows had mustered in sufficient numbers, there can be no doubt that his election could have been secured; but, as it turned out, only ninety-seven votes were recorded in his favour, of which sixteen were plumpers. We may assume, therefore, that there were not a hundred provincial members present on the occasion—a fact which need not cause much astonishment when we reflect upon the loss of time which would be incurred by the absence of country surgeons from their ordinary professional duties.

With regard to Mr. Gulliver, while lamenting that the College is deprived, for a time, of a distinguished ornament of modern scientific surgery, we candidly admit that we ourselves never thought very highly of his chances of success; and we are, indeed, no less surprised than gratified at observing the number of votes recorded in his favour—a circumstance which must, we think, be highly agreeable to his feelings, and must do more than reconcile him to a loss of office which, year after year, some members of the Council must henceforth inevitably experience. His exclusion from the Examining Board last year was, we believe, an unwise proceeding on the part of the Council, who ought to have recognised his eminent scientific position as a ready passport to his election as an Examiner in a College which professes to examine candidates in the theory as well as in the mere manual practice of their Profession. But the same feeling which actuated the Council in passing him over as an Examiner would induce them to withhold their support from his re-election as Councillor, and this feeling would be aggravated by the plain and straightforward manner in which he has lately expressed his sentiments towards the body with which he so lately acted. Then, as he is not an hospital surgeon, he could expect no support from the compact body of hospital officials and hangers-on, who would necessarily maintain what they consider to be their own interests. Thus excluded, as it were, by very powerful influences, to what quarter could he look for favour? As he is not a surgeon in metropolitan practice, he has had little opportunity of cultivating those personal professional friendships which are often of material service in a contested election; and as he has not held any position as teacher at the schools of medicine, he is comparatively little known to the present race of provincial surgeons. Hence, we repeat, that the large number of votes actually recorded in his favour must be regarded as a distinguished tribute of personal esteem for one who has pursued science for its own sake, and not for the immediate emolument which it sometimes brings; and who has been one of the pioneers of that brilliant dawn of physiology and pathology which, aided by chemistry and the microscope, is illuminating the condition of modern medicine and surgery.

The late election at the College is an unquestionable triumph for the Metropolitan Hospital Surgeons, to which class all the successful candidates belong. Whether it is desirable that the Council of the College should be exclusively recruited from this section of the Surgical Profession is very questionable, but the result must be taken as proving the formidable organisation which is at work in securing the election of this body to the College digni-

ties. Numerically, the Metropolitan Hospital Surgeons are very strong; and when they act in a compact body, as they evidently have done at the recent election, they can achieve almost any object they desire, unless it should happen, on future occasions, that a counter-organisation of provincial or independent Fellows should succeed in out-numbering or out-manœuvring them.

On the whole, we have no *Io pæans* to sing over the College election. The only principle that appears to have been established is, that when a man's term of office in the Council has expired, he has no chance of re-election; and perhaps this is only a righteous retribution on the part of the Fellows against the notorious tenacity of office and the abuse of re-elections which have characterised the Council in former times. But we look in vain among the newly-elected Councillors for any radical reformer who has the will or the ability to expose the present flagrant mismanagement of the College affairs, or to insist upon making the College the real representative of the wants, the wishes, or the aspirations of the Profession. The new Councillors will, in all probability, fall into the same groove with their predecessors, and will discreetly hold their tongues when it is inexpedient to speak out.

But Time, which works all kinds of wonders, will perhaps in after years accomplish that which, in the present state of matters, can scarcely be anticipated. The annual elimination of three members of the Council will infuse so much new blood into that body, that a continuance of the present abuses will be impossible, unless, indeed, the elections should virtually fall exclusively, as there is some reason to fear they may do, into the hands of a metropolitan clique, and unless the Council should continue to be over-ridden and held in awe (as they now unfortunately are) by the Court of Examiners. We explained last year, when some of our contemporaries were blundering about the subject, that this latter body is by no means so fixed in its position as it once was, and that a change in its composition might be effected if the Council had the courage to originate the movement. At the period to which we refer, we pointed out that the College of Surgeons is now governed by the provisions of *two* charters, one granted in 1843 and another in 1852. By the former of these charters the then examiners were continued in their office for life; but they are now all dead, except Mr. Lawrence. By the second charter, the then existing examiners elected subsequently to 1843 were to hold office at the pleasure of the Council; but all the examiners elected subsequently to 1852 were to retire from office every five years. As matters stand at present, Mr. Lawrence holds office for life; Messrs. South, Arnott, Hawkins, and Luke hold office at the pleasure of the Council; and Messrs. Skey, Hodgson, Wormald, Kiernan, and Paltridge, are subject to quinquennial removal from office, though allowed to present themselves for re-election. The Council, therefore, really have the power of removing nine out of the ten examiners, if they choose to exercise it; and we believe that they will fail in their duty if they allow the provisions of the charters, in this particular, to become a dead letter.

SUMMARY OF THE WEEK.

BLACKBALLING AT THE COLLEGE OF PHYSICIANS.

The scene we described as having occurred at the last meeting of the Fellows of the College of Physicians has excited considerable interest in the Profession, who are asking one another the cause of the disturbance on the occasion alluded to. It is a rule of the College that the Fellows are pledged by a solemn promise "not to divulge any of the proceedings of the meeting held for the election of Fellows and Members of the College," and therefore it is evident that the report of the meeting could not have emanated from any of the Fellows, and reporters are not admitted. How the cat was let out of the bag is, therefore, a curious subject of speculation; but we cannot help thinking that the publication of the names of persons blackballed is a most unwise proceeding, even although, as in the present instance, no personal affront was intended to the unsuccessful candidates. But we do not wonder that dissatisfaction has at last been expressed at the mode in which elections to the Fellowship are conducted. The plain and obvious course for the Council to adopt in future would be to recommend for the honour of the Fellowship those who are able to pass a high examination. The bye-laws of the College represent as eligible for the Fellowship all "members of at least four years' standing, who have distinguished themselves in the practice of medicine, or in the pursuit of medical and general science or literature;" but we nevertheless find that persons who have distinguished themselves in neither are continually put up for election, while many of those who have distinguished themselves in both, and who are willing to have their qualifications tested by stringent examination, are excluded. While the present arbitrary system continues, we do not wonder that the Fellows are discontented with the mode of election.

THE ARMY MEDICAL SERVICE.

From the report of an interview granted by Lord De Grey and Ripon, the Secretary at War, to a deputation of the Metropolitan Branch of the British Medical Association, and which will be found in another part of our Journal, it does not appear that the Government holds out much hope of redress for the grievances endured by the Officers of the Army Medical Service. The meeting was a highly respectable and influential one, comprising the President of the Medical Council, the President of the Royal College of Surgeons, and several of the Medical Officers and teachers of the Metropolitan Schools of Medicine, who represented in firm but courteous terms the disabilities under which the Medical Officers of the Army at present laboured, and the disappointment they had experienced in the withdrawal of the Warrant of 1858. Lord De Grey and Ripon seemed, however, to have been well primed by the authorities at the Horse Guards as to the military arguments to be advanced in answer to the remonstrances of the deputation, and he repeated the well-known sentiments on the subject of Army Medical Reform, which have already been expressed by the combatant branch (as

they are called) of the service in the Houses of Parliament. He was deaf to all the representations made to him as to the falling-off of candidates for the Medical Service, and declared the determination of the Government not to yield to what they considered to be an attempt at intimidation or coercion exercised by the Medical Officers of the Army. But a time may come when the Government will find that they must adopt another tone, and must concede claims which cannot much longer be resisted.

ALLEGED NEGLECT OF A POOR-LAW MEDICAL OFFICER.

In reference to an article which appeared in our Journal with the above heading, on the 29th ult., and which included some extracts from an inquiry instituted at Holbrook, as to certain charges made against Dr. Albert Fleming, we have much pleasure in stating that the conclusion arrived at has been entirely in favour of that gentleman. Sir John Walsham, who was deputed by the Poor-law Board to conduct the inquiry at the Sandford Hundred Union Workhouse, Tattingstone, has reported that the Board at Whitehall have concurred in the favourable opinion entertained and expressed by the local Board, and that they completely exonerate Dr. Fleming from all blame in the case of the patient, who unfortunately died from flooding in childbirth. This conclusion has been recorded in the minutes of the local Board, and a copy has been directed to be sent to Dr. Fleming. The worst feature in this case is, that the charges made against Dr. Fleming were sustained by a medical practitioner living in the same village with himself, and that the latter has not thought proper to explain or justify the steps he took in the matter. It is bad enough for medical men to be misrepresented and persecuted by the public, but it is still worse to have to defend ourselves from injustice and injury inflicted from among our own ranks.

THE REPORT ON CHLOROFORM BY THE COMMITTEE OF THE MEDICO-CHIRURGICAL SOCIETY.

On Tuesday, the 5th inst., an abstract of the report on chloroform by a committee of the Medico-Chirurgical Society was read at a special meeting of the Society. The report is exceedingly voluminous, and is the result of no less than seventy meetings of the different sections into which the committee was divided, the physiological section having especially devoted great attention to the subject, and having performed a great number of experiments. The questions comprised in the report were chiefly the following —viz.: How chloroform destroys animal life; the effects of chloroform on the action of the heart and on the respiration; the effects of division of the pneumogastric nerve; the effects of chloroform on the glottis and fauces; the effects of ether; the post-mortem appearances in animals destroyed by chloroform; the mode of resuscitation in apparent death from chloroform; the rules to be observed in cases of threatened death from chloroform; the uses of chloroform in surgery and in midwifery.

In reference to the action of chloroform on the heart, and on the comparative merits of chloroform and ether as anæsthetics, the committee make the following remarks :—

"The first effect of chloroform vapour is to increase the force of the heart's action, but this effect is slight and transient, for when complete anæsthesia is produced the heart in all cases acts with less than its natural force. The strongest doses of chloroform vapour, when admitted freely into the lungs, destroy animal life by arresting the action of the heart; whilst by moderate doses the heart's action is much weakened for some time before death ensues; respiration generally, but not invariably, ceasing before the action of the heart, death being due both to the failure of the heart's action and to that of the respiratory function. The danger attending the use of chloroform increases with the degree of stupor it induces; the apparent irregularities in the action of the anæsthetic mainly depending on the varying strength of the vapour employed, on the quality of the chloroform, and on the constitution of the patient. In order that it may be administered with comparative safety, it is necessary that the percentage of vapour should not exceed three and a half per cent., that its effects should be carefully watched, and the inhalation suspended when the required anæsthesia is induced. In many respects the action of ether is similar to that of dilute chloroform. At first its vapour increases the force of the heart's action, an effect which is both greater and of longer duration than that observed with chloroform. The stimulation is followed by a depression of the force of the heart's action, but, at the same degree of insensibility, ether does not depress the action of the heart to the same extent as chloroform; eventually, ether kills partly by enfeebling the action of the heart, but chiefly by arresting the movements of respiration. Thus the energy with which chloroform acts, and the extent to which it depresses the force of the heart's action, render it necessary to exercise great caution in its administration, and suggest the expediency of searching for other less objectionable anæsthetics. Ether is slow and uncertain in its action, though it is capable of producing the requisite insensibility, and is less dangerous in its operation than chloroform. On the whole, however, the committee concur in the general opinion which in this country has led to the disuse of ether as an inconvenient anæsthetic. A mixture of ether and chloroform is as effective as pure chloroform, and a safer agent when deep and prolonged anæsthesia is to be induced; though slow in its action, it is sufficiently rapid in its operation to be convenient for general use. A mixture composed of ether three parts, chloroform two parts, alcohol one part (by measure), is to be preferred, on account of the uniform blending of the ether and chloroform when combined with alcohol, and the equable escape of the constituents in vapour, and the committee suggest that it should be more extensively tried than it has hitherto been in this country."

The committee believe that the effects of chloroform depend much more on the degree of its concentration than on the mode of administering it, and that an apparatus is not essential to safety if due care is taken in other respects. Free admission of air, together with the chloroform, is absolutely necessary. The apparatus employed by Mr. Clover possesses the advantage of measuring the amount of vapour inhaled, but the objection to it is that it is not very portable. In the absence of any accurate means of determining the quantity of chloroform vapour administered, the committee thought the plan of administering the anæsthetic on a handkerchief or lint the least liable to objection; but it should be held an inch and a half from the mouth, so as freely to admit the air.

In regard to resuscitation after apparent death from chloroform, the committee believe that the most certain means of restoring life is by artificial respiration, and that Dr. Silvester's method, if applied early, is the most efficacious measure. By this plan resuscitation may generally be accomplished after natural respiration has ceased, provided the heart continues to act; and it may sometimes be effected even after the cessation of the heart's action. Galvanism is far less to be relied on than artificial respiration in equal cases, but with either remedy it is found that animals quickly rendered insensible by a strong dose are more easily recovered than those which have been gradually narcotised even by a small percentage of the anæsthetic. As to the amount of chloroform which might be inhaled with safety, it was found practically that a mixture containing from 2 to 4 per cent. of chloroform vapour and 96 or 98 per cent. of air might be inhaled without danger to life; and, if necessary, 4 or 5 per cent.

of chloroform vapour might safely be used; but 10 per cent. was liable to produce dangerous symptoms.

As to the uses of chloroform in practical medicine and surgery, and the contraindications supposed to exist against its use in certain cases, the committee consider that, in surgical practice, the administration of chloroform is not contraindicated by the presence of heart-disease; but fatty degeneration of the organ requires care. The question, however, is to determine the symptoms by which fatty degeneration may be detected during life. Chloroform may be given, with proper management, in operations on the mouth and throat. In operations on the deeper parts of the eye, it is undesirable, from the vomiting which may be induced. In hernia, it is highly valuable; and in operations about the anus it is indispensable. The examination of the results of 2,586 capital operations performed before chloroform inhalation was introduced, and of 1,860 operations of similar character performed subsequently, proved that the rate of mortality had not been increased since the introduction of chloroform; and it is needless to expatiate upon the diminution of suffering obtained by this invaluable agent.

In obstetric practice, the use of chloroform in natural labour is not attended with danger; no well-authenticated cases of death from its use having come to the knowledge of the committee, although sometimes unfavourable symptoms have been produced. It may, in moderate doses, protract labour; but does not always do so. It does not predispose to convulsion, nor does it interfere with lactation or with the general condition of the mother and child. In artificial labour, the inhalation of chloroform is very useful in many cases; but, as a rule, should not be employed when there has been much hæmorrhage, unless stimulants are also given. Chloroform is also useful as a means of facilitating diagnosis in diseases of women; and, both inhaled and applied as a liniment, is serviceable in severe cases of dysmenorrhœa, neuralgia, &c. Chloroform inhalation was also favourably reported on as a remedy in the convulsive diseases of women and children, and this opinion is in accordance with the views of most practical obstetricians.

These are some of the leading points touched upon in the report, but we shall revert to this important subject on an early occasion.

GENERAL CORRESPONDENCE.

A CASE OF DISTRESS.

To the Editor of the Medical Circular.

SIR,—Acting under the advice of several members of the Medical Profession, I forward the enclosed appeal, earnestly soliciting that you will give it a place in the columns of your valuable paper; and also requesting that you would kindly consent to receive contributions for the bereaved widow.

I am, &c.,
HENRY BROMFIELD.

Blockley Vicarage, Moreton-in-Marsh.
July 5, 1864.

The Rev. H. Bromfield, Vicar of Blockley, begs to call the attention of the members of the Medical Profession to a case of great destitution, and solicits their contributions on behalf of the bereaved widow and children.

Mr. Edgar Bull, surgeon, resided and practised in the village of Blockley for several years. On a foggy night in January, 1863, on his way home from a patient, he fell down a bank and sustained a bad fracture of the leg. A long confinement to his bed, and the consequent loss of income, preyed upon his health and spirits; and although he partially regained the use of his limb, the constitution received so severe a shock, that his mind gave way, and in a paroxysm of mental aberration he precipitated himself from a window and was killed.

Mr. Bull has left a widow and four children. The eldest son (nineteen) is in a draper's shop, but two daughters, a son, and the widow are utterly destitute. The Editor of the MEDICAL CIRCULAR has kindly consented to receive contributions, which will be applied to establish the widow in a grocery business, in the hope that she may support herself and keep a home for her children until some provision can be made for them.

Contributions will be also received by Admiral Collier, C.B., Rev. H. Bromfield, Blockley; Charles W. Morris, Esq., Surgeon, Chipping Campden; Dr. Moore, 15 Charles terrace, Victoria park, London; Dr. Kingsley, Stratford-on-Avon.

Blockley Vicarage, Worcester,
July 5, 1864.

CHLOROFORM AND EAU DE COLOGNE.

To the Editor of the Medical Circular.

SIR,—An inquiry has recently arisen whether chloroform was ever tried, or if it be useful, in epilepsy. A very extended and detailed examination of cases under that agent, favourable to its use, is to be found in the excellent work of Dr. Reynolds; it is, on the other hand, very dangerous in chorea and delirium tremens. In the former the part of the brain that presides over emotion and respiration is weakened already, and chloroform extinguishes life. Very marked cases of epilepsy are now cured by a slight surgical operation, the suggestion of Dr. Brown-Séquard. It is asked also how to use eau de cologne and chloroform together. The best plan is, perhaps, in about equal parts, but sprinkled separately on a napkin folded in shape of a cone.

I am, &c.,
Sackville street, CHARLES KIDD, M.D.
June 24.

PS.—As to the other "mixtures," what is true about them is not new, and what is new is as old as an extensive trial of them in France and especially in Austria, even by Austrian Government order; but they are cumbrous, and the spirits of wine is simply squeezed out of the sponge after the chloroform and ether have been inhaled. They lead to quackery also, by the idea that the chloroform is supposed "to take" without entering the blood,—about as wise as to say a lancet could open the femoral vein without entering or disturbing the blood; but so the lancet fraternity will have it.

GRIFFIN TESTIMONIAL FUND.

To the Editor of the Medical Circular.

SIR,—The following subscriptions have been already received on behalf of the above fund:—

	£	s.	d.
Henry Blenkarne, Esq., City of London .	1	1	0
Henry Sutherin, Esq., St. Pancras . .	1	1	0
J. Clark, Esq., Shoreditch . . .	1	0	0
Dr. Robert Fowler, East London . .	1	1	0
A. M. Champneys, Esq., Whitechapel .	0	10	6
T. M. Kendall, Esq., King's Lynn . .	0	2	6
S. B. Humphreys, Esq., City of London .	1	1	0
Dr. David King, Lewisham . . .	0	10	0
J. G. Gerrans, Esq., St. Marylebone . .	0	5	0
Henry Terry, Esq., jun., Hardingstone .	0	10	0

I am quite willing to take the entire management of the fund, if generally desired.

Yours obediently,
ROBERT FOWLER, M.D.,
145 Bishopsgate st. Without, Treasurer and Hon. Sec.
July 6, 1864.

MEDICAL PROVIDENT ASSOCIATION.

To the Editor of the Medical Circular.

SIR,—About this time last year an effort was made to form a Medical Provident Association. I am glad to inform your numerous readers that that noble effort has not been abandoned, but only set aside until a safe plan could be devised which would confer the greatest boon ever known to the Profession. It will be remembered that Mr. Carter, of Stroud, took a prominent part in the business; and from the correspondence which I have had with him, I am at liberty to send you the enclosed letter for publication. As the business will be brought forward next month, I hope, Mr. Editor, that we shall have a spirited leader from you

in an early number to help it forward. If such an association had been in existence, I doubt not you would have been spared the painful duty of appealing on recent occasions to the Profession and the public on behalf of many a widow and her helpless family.

One thousand subscribers will be required to place the association on a firm and permanent basis; and I hope, when your trumpet sounds, that ten thousand will arm themselves with golden weapons and be ready to do battle on such charitable ground. Wishing you continued and increasing success, I am, Mr. Editor, Yours, &c.,

Oswestry, July 8, 1864. ALPHA.

SIR,—In reply to your inquiry, I have to say that my visit to London convinced me of the entire practicability of the scheme proposed, and obtained for me the knowledge that such an institution has been successfully worked among the clergy for thirty years. The experience of their society will be available, at the proper time, in the formation of ours.

Almost immediately after I went to London, the meeting of the British Medical Association was held at Bristol. There, Dr. Richardson proposed the appointment of a committee, consisting of Sir C. Hastings, Mr. Daniell, Dr. Richardson himself, myself, and other gentlemen, to inquire into the whole subject, and to report to a special general meeting. It was carried as an amendment that the report should be referred to the next annual meeting.

It seems to me that the report of the committee will have so much more weight with the Profession than the labours of one man, that I determined to hold my hand in the matter, and wait the year. I purpose to ask the committee to report not only upon general principles, but upon organization, and I shall take care that their report is extensively circulated, and that action is taken upon it. I have obtained the promise of influential assistance for a London meeting, to follow that at Cambridge; and I hope the institution will be able to begin work with the beginning of next year.

I feel that I should only be beating the air, and wasting my own fully-occupied time, by any endeavour to precipitate matters. The actuaries tell me that we must have 1,000 members before the society will rest on a basis independent of casualties.

The appointment of the Bristol committee, was I believe, noticed in the Journals at the time, and I thought it unnecessary to publish anything more, although I have great pleasure in replying to your inquiry. If you think it would answer any useful purpose to send this note to one of the Journals, perhaps you would kindly take the trouble to do so. I am, &c.,

Stroud. R. B. CARTER.

THE LATE SURGEON OF THE ALABAMA.

To the Editor of the Medical Circular.

SIR,—Perhaps some of your readers may not be aware that a Committee has been formed for the purpose of raising funds, both from the Profession and from the general public, for some appropriate memorial in honour of the late David Herbert Llewellyn, surgeon of the Alabama. We shall be happy to receive subscriptions here at the Hospital, or they may be sent to the Imperial Bank, 6 Lothbury and 53 Parliament street.

We are, Sir, &c.,
W. TRAVERS, F.R.C.S., O. W. BERRY,
Hon. Secs. to the Llewellyn
Memorial Fund.

Charing-cross Hospital,
July 4th, 1864.

PUNISHMENT OF ILLEGAL MEDICAL PRACTICE IN FRANCE.—The correctional tribunal of Gourdon (Lot) has sentenced to six days' imprisonment, to twelve shillings fine, and to the payment of all the costs of the prosecution, a dispensing chemist of Souillac, indicted for the illegal practice of meditine.

THE ARMY MEDICAL SERVICE.

DEPUTATION TO THE SECRETARY OF STATE FOR WAR.

On Tuesday, the 5th inst., a deputation of members of the Metropolitan Counties Branch of the British Medical Association had an interview with the Right Hon. the Earl De Grey and Ripon, Secretary of State for War, on the Army Medical Service. The deputation, which was introby Dr. J. Abel Smith, Esq., M.P., consisted of Dr. Sibson, President of the Branch; Dr. Burrows (President of the Medical Council); Mr. Skey (President of the Royal College of Surgeons); Drs. Camps, Andrew Clark, Hare, Harley, Henry, Richardson, Routh, Hyde Salter, Joseph Seaton, Stewart, and G. Webster; and Messrs. Holmes Coote, Curling, Dunn, H. Lee, Lord, W. Martin, Millar, and C. H. Moore; as well as Drs. Chowne and Sharpey, and Mr. Barwell.

Dr. Sibson said that the Metropolitan Counties Branch had taken up the subject of the Army Medical Service for two reasons—first, because the medical officers of the army were precluded, by considerations of discipline, from stating their own grievances; and secondly, because the Branch contained among its members gentlemen connected with all the London hospitals and medical schools, who consequently were constantly in contact with those who might become candidates for admission into the army. Some time ago the teachers in the schools have been accustomed to urge their pupils to enter the army; but now circumstances were altered, and they could no longer do so. The Association of which this was a Branch had always taken much interest in all that related to the welfare of the Profession. Dr. Sibson then presented the following memorial:—

To the Right Honourable the Earl De Grey and Ripon, Secretary of State for War.

The Memorial of the President and Members of the Metropolitan Counties Branch of the British Medical Association.

HUMBLY SHEWETH—

That the attention of your memorialists has been drawn to the condition of the Medical Service of the Army.

That it is well known to your memorialists, that the number of candidates for admission into the Medical Service of the Army is far from being commensurate with the number of vacancies; and that, in consequence, gentlemen engaged in civil practice have been invited to undertake the charge of troops at home.

Your memorialists are of opinion that the members of the Medical Profession have ceased to apply for admission into the Medical Department of the Army, because, owing to the successive changes in the Warrant of 1858 (which Warrant gave general satisfaction), and to the practical departure from that Warrant by the Executive, they have lost confidence in the good faith of the military authorities.

They are further of opinion, that the frequent non-enforcement of the precedence granted by the Warrant of 1858, and the modification of that precedence by the Warrant of 1863, disqualifying the medical officer from presiding at boards (although on other than purely military matters), even when he is the senior officer present, have, by lowering his status, done more than any other grievance to deter members of the Medical Profession from joining the service.

Your memorialists are further of opinion—

1. That the Warrant which expresses the terms of service under which medical men enter the army should in future be clearly defined, so that no misapprehension may arise.

2. That no alteration should be made in such Warrant without an inquiry, which inquiry should be open to the Medical Service, and should be of the same extent, and involve the same amount of consideration, as that which led to the first promulgation of the Warrant.

3. That any such alteration should be made with formality and publicity, and after an explanatioon to the medical officers of the grounds on which it has been considered necessary to alter the terms of service.

Your memorialists are further of opinion, that the Warrant of 1858 should be the basis of future regulations

for the Army Medical Department, subject to the following modifications:

1. The proper definition and enforcement of the precedence of the medical officer, in accordance with his rank, at boards, mess, and committees of all kinds.
2. Increased pay of assistant-surgeons and surgeons.
3. Promotion to the rank of surgeon after, at most, ten years' full-pay service.
4. Optional retirement after twenty years' full-pay service on an adequate pension.
5. Controlling power and free agency to the medical officer in his own department.
6. Regular leave for the medical officer, and sick leave on the same footing as is granted to all other officers.
7. Non-deduction of pay for expenses incurred in the execution of his duty.
8. The abolition of the system of confidential reports by the surgeon on the conduct of the assistant-surgeon.
9. The infliction by the military authorities of all punishments ordered by them; the medical officer's duty on such occasions being limited to the protection of the soldier from serious injury.

Your memorialists are further of opinion, that the systematic employment of deputy or acting assistant-surgeons without examination ought to be discontinued; since it will inevitably introduce an inferior class of medical men into the service, and inflict great hardship on the military medical officer by increasing indefinitely the period of foreign service, and so still further deter medical men from entering the army.

Finally, your memorialists would especially insist that although, since the issue of the Warrant of 1858, an examination has very properly been instituted, the intention and effect of which have been to exclude from the Medical Service of the Army all but highly qualified candidates, the inducements to enter the service have been considerably lessened. The inevitable consequence of thus discouraging the better members of the Medical Profession from entering the army is, that the soldier must suffer. And your memorialists are persuaded, that the services of thoroughly competent men of high tone and character will not be obtained until the medical officer is upheld by the military authorities, and is permanently placed in that honourable position which is due to himself and to the Profession to which he belongs.

Your memorialists therefore respectfully urge your Lordship to take this memorial into your favourable consideration, and to adopt such measures as will tend to secure at once the welfare of the soldier and the interests of the Medical Department of Her Majesty's Army.

Signed on behalf and by the authority of the members of the Metropolitan Counties Branch,

FRANCIS SIBSON, M.D., F.R.S., *President.*
A. P. STEWART, M.D., } *Secretaries.*
ALEXANDER HENRY, M.D., }

Dr. Burrows, President of the Medical Council, cordially supported the prayer of the memorial.

Mr. Skey, as President of the Royal College of Surgeons, expressed the deep regret of himself and his colleagues in the Council of the College at the condition of the medical officers of the army.

Lord De Grey and Ripon said that he was glad to have an opportunity of seeing so many members of the Medical Profession, and of discussing the present subject with them. The memorial involved two points: 1. The renewal of the Warrant of 1858; 2. Increased pay, &c. He would ask in what respects it was considered that the Warrant of 1858 was not carried out?

Dr. Stewart: With regard to relative rank.

Lord De Grey and Ripon said that Clause xvii. was then the portion of the Warrant referred to. In 1861, a warrant was issued, by which the surgeon ranked as junior major. This, as the deputation was probably aware, was repealed by the Warrant of 1863. He supposed that the principal objection to the latter was in regard to the part treating of the position of the army medical officer on boards, &c.

Dr. Stewart said that was the point of objection. The deputation had also been informed that the medical officer ranked as junior in mess; and there was reason for questioning whether the Warrant was carried out in its integrity. But the right of the medical officer to be president of boards was the main point.

Lord De Grey and Ripon: The Warrant of 1858 laid down that medical officers were non-combatant; and he presumed that they did not wish to interfere with military command. He could not understand why so much importance was attached to the presidency of boards.

Dr. Stewart would remind his Lordship that, if a superior class of medical men was to be induced to enter the army, proper marks of distinction and social courtesy must be extended to them.

Lord De Grey and Ripon understood, from what had been said, that the deputation did not desire that the presidency of courts-martial or of boards on purely military matters should be open to the medical officers; but that on certain boards—sanitary, for instance—the medical man should be placed according to his rank. He would give the proposal to renew the Warrant of 1858 his best consideration; but he feared he could not support some of the other doctrines laid down in the memorial. He would ask whether, within the last few years, there had not been an increase in the number of good appointments elsewhere, which had drawn off medical students from entering the army; and whether, at the same time, there had not also been a diminution in the numbers of those entering the Profession.

Dr. Hare said that formerly students used to enter the medical schools with the view of joining the army; but now this was not the case.

Dr. Richardson said there had certainly been a very serious decrease in the number of the Medical Profession; since 1854, he believed, the decrease had not been less than four thousand. This was very important as regarded competition; but it did not affect the duty of the authorities to render the army attractive to medical men.

Lord De Grey and Ripon was quite ready to allow that it might be necessary to offer increased pecuniary advantages to medical men entering the army. But he believed that there was an organised agitation going on among the Army Medical Officers; and the Government must set its face against anything of this kind.

After some further discussion and explanation of several portions of the memorial, Lord De Grey and Ripon said that the return to the Warrant of 1858, and the proper establishment of the precedence of medical officers, were questions that might well be considered. On other points, he would not encourage the deputation in hoping for a change.

The deputation, having thanked his Lordship, then withdrew.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 17.

Mr. PRESCOTT HEWITT, President, in the Chair.

Mr. HOLMES exhibited

THE PARTS CONCERNED IN A PLASTIC OPERATION FOR THE RELIEF OF THE DEFORMITY OF EXTROVERTED BLADDER.

This was the first operation of the kind successfully performed in this country, and was reported soon after the time of its performance in the 'Lancet,' June 27, 1863. Its principle was to cover the exposed bladder by means of a flap (taken out of the groin on one side) turned down with its skin surface inwards; and to fix this flap by another (taken from the opposite scrotum) drawn over the former flap with the skin surface outwards. After the union of these two flaps, a broad thick cover will be formed, which can then be easily united with the skin of the abdomen, by one or more operations, leaving a hiatus below for the escape of the urine. To this a common "railway urinal" can very easily be adapted. If the flaps are pretty thick,

and the patient in good health, they will generally unite very readily; and their union appears both more probable and more secure than that of flaps united only by their edges. In cases complicated with large hernial protrusions, distending and thinning the skin, and in persons reduced by ill-health, union is very doubtful. In the preparation exhibited, the cleft was entirely covered. The hiatus left was large enough to admit the finger easily, and Mr. Holmes thought it better to have an opening of this size, since the bladder ought to be frequently washed out with a syringe to clear it of phosphatic deposit; and if the opening be reduced too much, this deposit will be more troublesome. But when the cover is once formed, the opening can be contracted as much as the surgeon pleases. There was a very minute pin-hole opening in the union between the transplanted cover and the skin of the abdomen, but it was hardly visible, and did not appear to transmit any urine. The patient, a well-grown boy, nine years of age, died about a year and a quarter after the operation, from the growth of a tumour of the fibro-plastic variety, in the pons varolii and cerebellum.

Mr. WOOD exhibited a

SPECIMEN FROM A CASE OF EXTROVERSION OF THE BLADDER AFTER OPERATION.

The specimen was from the body of a male child, aged seven years, who died in King's College Hospital from erysipelas of the head and face about six weeks after the completion of the plastic operations for the cure of the deficiency of the front wall of the bladder. Before operation the case presented all the usual characters of this result of arrest of development, viz., deficiency of the symphysis and wide separation of the arches of the pubes and of the origin of the recti muscles; complete exposure and protrusion of the hinder wall of the bladder and orifices of the ureters; separation of the corpora cavernosa and deficiency of the upper wall of the urethra. The testes were still in the canal or abdominal rings; the scrotum empty. The operations were as follows:—First, two lancet-shaped flaps were cut from the skin of the groin, with their bases towards the scrotum; these were then transplanted so as to join each other by a broad surface for adhesion over the exposed bladder. When these had become united, a flap was turned down from above, after Pancoast's method, and drawn under the united side flaps, thus closing up the upper aperture left in the first operation. Then a flap was taken from the scrotum on each side, turned over the imperfect penis, and stitched with their raw surfaces together. These became adherent to each other, and united to the upper flaps so as to form a sort of short tube for the urethra. No sloughing occurred, and all had completely healed a month before the occurrence of the disease which destroyed the little patient. He had power of retention to the extent of a couple of ounces, until a cough or the elasticity of the sides of the new cavity caused a gush through the newly-formed urethra. He was waiting for the fitting of an India-rubber bottle when attacked by the erysipelas which carried him off. Mr. Wood attributes a good deal of the success which followed the transplantation to preservation of the ascending branches of the common femoral artery which supply the lower part of the skin of the belly. These were kept undivided in the area of the base of the side flaps so as to preserve their vascularity undiminished. He mentioned that he had another case of the kind now under treatment in the hospital, which had been equally successful.

Mr. HUTCHINSON exhibited a specimen of

COMPLETE DETACHMENT OF THE LOWER EPIPHYSIS OF THE FEMUR.

A lad, aged twelve, was brought into the London Hospital, having been run over in the street. He had sustained what, at first sight, was supposed to be a compound dislocation of the left knee-joint, and the soft parts were most severely injured. On examination, it was found that the projecting bone was the end of the shaft abruptly detached from its epiphysal extremity. The latter still remained in connection with the tibia, and the joint itself was uninjured. Primary amputation was necessitated, and was at once performed (by Mr. Adams, in consequence of Mr. Hutchinson's absence from town). In dissecting the parts, the popliteal artery and vein were found torn across, and the periosteum had been very extensively stripped from the lower part of the shaft. The epiphysis itself had been displaced by the gastrocnemius in such a manner that its surface of detachment looked directly backwards into the popliteal space, instead of upwards in a line with the shaft. Mr. Hutchinson drew particular attention to this displacement, and showed that it would have been quite impracticable to treat such an injury in any other position than with the knee bent at right angles (double inclined plane). He also remarked upon the circumstance that the periosteum was so extensively torn off, and said that he believed this was a common result in these accidents, and that it explained the frequency with which suppuration between the periosteum and bone occurs after them.

(To be continued.)

OBITUARY.

THE LATE DR. A. MACDOWALL, OF HELENSBURGH.

It was our melancholy duty, a few days ago, to announce the death of this amiable and accomplished Medical Practitioner, who died at his residence at Helensburgh on the 10th inst., after a long and tedious illness. Born in Glasgow, where his father pursued a similar calling, Dr. Macdowall was early destined for the Medical Profession, and completed his studies with honour and success at the University, as well as at the Royal Infirmary of this city, where he acted for the full period as House-Surgeon, and acquired, as he always took pleasure in saying, the most useful portion of his Medical and Surgical knowledge. On the breaking out of hostilities in the Crimea, he volunteered his services as Surgeon to the Turkish Contingent force, under command of British officers, which was quartered at Kertch and Yenikale, and which proved of considerable service during the war. In his capacity of Regimental Surgeon, Dr. Macdowall distinguished himself by his exertions in promoting the sanitary condition of the troops, which, in consequence of the experimental character of the service, were sadly decimated by cholera and fever. For these and similar duties in the field he was specially mentioned in the despatches of the Director-General, and was among the few who were selected to receive from the Sultan the decoration of the order of the Medjidie, an honour which, in his case at least, was universally acknowledged to be well deserved. Immediately after the cessation of hostilities, Dr. Macdowall was solicited by the Turkish authorities to continue his connexion with the Government, with the view of assisting in the organisation of a proper medical staff for the native army, but he preferred returning to England, an alternative forced on him in consequence of severe family bereavement. He afterwards settled at Helensburgh, in which he practised his Profession for several years; but it is to be feared that the cares and anxieties of a rapidly increasing country practice, acting on a not very robust constitution, had the effect of cutting short, at the early age of thirty-three, a useful and well-spent life. To a singularly acute knowledge of his Profession, Dr. Macdowall combined in an eminent degree a cheerful and obliging disposition, coupled with strict integrity and high moral worth. His memory will be long treasured as a precious possession by his family and by his patients, as well as by a large circle of attached friends.—'Glasgow Paper.'

ROYAL INSTITUTION OF GREAT BRITAIN.—A general monthly meeting was held on Monday, July 4, 1864, William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair. General Sir Edward Lugard, K.C.B., and John Ruskin, Esq., were elected members of the Royal Institution.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 30th ult.:—Augustin Barber Fry, Sleaford, Lincolnshire; George Grewcock, Folkingham, Lincolnshire; Francis John Marshall, Moulton, Northamptonshire; Samuel Rooth, Chesterfield.

The following gentlemen also on the same day passed their first examination:—John King, King's College; Frederic Edward Manby, Guy's Hospital; John Oakley, King's College; George Jesse Barnabas Stevens, Guy's Hospital.

THE PROGRESS OF HUMANITARIAN PRINCIPLES.—The Federal Council of Switzerland have addressed an invitation to the German Confederacy to send a delegate to the International Congress, which is to be held at Genoa on August the 8th, for the object of laying down principles and concerting measures, in the interest of humanity, with reference to the better tending of the wounded on the fields of battle. The German Confederacy have appointed a special committee to report on the question.

DISPOSAL OF THE DEAD IN CALCUTTA.—We learn from the 'Calcutta Englishman' "that the Government of Bengal has taken active measures with regard to the dead bodies that are thrown into the river. The police have been reminded that this duty was within their province, and that the Government would not see neglect further continued with satisfaction. It is ordered that a stop be put to the practice, and steps be immediately taken for the proper disposal of the dead."

DIGITALINE.—Mr. Lefort, at one of the recent meetings of the Institute of France, forwarded a paper "On Digitalinum," of which two kinds appear to be in use. One is soluble, and imparts to concentrated hydrochloric acid a yellow colour, which passes to a fine green. This species is chiefly prepared in Germany. The other kind is insoluble, and is prepared in France, and receives from muriatic acid a more intense green colour, whence it may be presumed to be purer. Viewed through the microscope, German digitalinum presents itself under the form of translucid crystals; French digitaline, on the contrary, assumes the aspect of an opaque mass, and emits a strong smell of foxglove leaves. These characteristics may assist in detecting the presence of this substance in colourless liquids.

PREVALENCE OF SMALL-POX AT STAFFORD.—The small-pox is prevalent at Stafford; many fatal cases have occurred. What are the statistics of vaccination in that town?

HASLAR AND NETLEY HOSPITALS.—The annual cost of the administration of Haslar, including salaries, wages, taxes, and contingencies, amounts to 14,000*l.* There is accommodation for 1,000 patients. The annual cost of the establishment at Netley, which could contain a still larger number, amounts to about 12,000*l.* a year.

MORTALITY OF STOKE-UPON-TRENT.—Dr. Arlidge, senior physician to the North Staffordshire Infirmary, has just published details of the mortality of Stoke-upon-Trent, chiefly with reference to children and potters. He says that "the mean age of the adult population is forty-six years and a half, while that of adult males in England equals fifty-six. Consumption and diseases of the lungs were the cause of death in 13·50 per 1,000 male potters living, or 1,350 in 100,000. Above 40 per cent. of the whole number of deaths from diseases of the respiratory organs amongst adult males of all occupations happen among male potters. Nearly 60 per cent. of males thus occupied die from diseases of the respiratory organs.

VACCINATION AT GATESHEAD.—From a report by Dr. Henry Stevens, Inspector of Public Vaccination, it appears that at Gateshead during the three years ending Sept. 30th, 1863, there had been registered in the Union 7,600 births, and 5,879 infant vaccinations had been performed by the public vaccinators, being 77·3 per cent. of the births.

ACADEMIE DES SCIENCES.—At the last meeting of this learned body, M. Wöhler, of Göttingen, was elected foreign associate in the place of the late Professor Mitscherlich. The other candidates were De la Rive, Geneva; Agassiz, Boston; Airy, Greenwich; Bunsen, Heidelberg; Hamilton, Edinburgh; Martins, Munich; R. Murchison, London; and Struve, Pultava.

TESTIMONIAL.—On the retirement of Dr. Coucher from the duties of Union Medical Officer of the Melcombe Regis District, the following satisfactory acknowledgment of his services was agreed upon at a meeting of the Board of Guardians held on Tuesday, June 14:—On the motion of H. C. Godden, Esq., seconded by Mr. R. Thomas, it was unanimously resolved,—"That the thanks of the Board be given to Dr. Coucher for the kindness and attention uniformly shown by him for the past six and a half years to the poor of the parish of Melcombe Regis, and that the clerk be requested to convey the same to Dr. Coucher."—(Signed), H. C. Gooden, Chairman.

THE AMERICAN MEDICAL ASSOCIATION.—The American Medical Association, founded in 1847, held its fifteenth annual meeting at New York on June 7, 8, and 9, and seems to have gone off satisfactorily, although the papers which were read are said to have been characterised by marks of haste in their preparation. Delegates came from every part of the Federal States, and the meeting, under the presidency of Dr. Davis, altogether was a successful one. It voted that the introduction of compulsory vaccination into the United States is impracticable, and appointed a committee to memorialise the President in favour of an increase of rank and pay for the medical staff of the army and navy. A motion was carried reprehending the project of rewarding Dr. Morton by a vote of 200,000 dollars now pending in Congress, the Association being of opinion, in the first place, that he had placed himself beyond the pale by taking out patents for anæsthetics and prosecuting charities for invading them, and next that he had been amply rewarded already through private benificence in Boston, New York, Philadelphia, and elsewhere. Numerous committees were appointed to report to the next meeting on various subjects; amongst which were drainage and sewerage, the relations of alcohol, quarantine, microscopical investigations, the aboriginal races, international medical ethics, climatology and epidemics, &c.

BOMBAY SANITARY COMMISSION.—A Sanitary Commission has been appointed for the Bombay Presidency. It is presided over by Dr. Leith, with Dr. Beatty as Secretary, these two officers being relieved from other duty. The other members are Major Martin, of the 4th, and Captain Close. The duties of the Commission are not defined, but they are evidently of a general and not local character.

SURGEONS ON THE FIELD OF BATTLE.—*Apropos* of the necessity for the presence of surgeons on the field of battle, I may mention meeting at Wilderness, under shelter of the breast works, two cases of active hæmorrhage from gunshot wounds—in one the radial required to be ligatured; in the other the brachial. In both cases the loss was profuse, and had begun to tell upon the strength of the man. An aperture of exit for a rifle ball, not generally spoken of in books, is the mouth. In a case occurring two days ago, ball entered left side of the neck, and two or three hours after was coughed up by the patient. For the first time I have seen a death upon the operating table from chloroform. Patient was undergoing an amputation of right arm at shoulder-joint. Chloroform ceased to be administered when the first sleep was made. The arm was removed, and arteries tied, when the patient was discovered to be pulseless. Artificial respiration was had recourse to, but without avail. The man's pulse was good before the operation commenced. He walked without assistance to the table, and he lost but very little blood after arriving there. At the autopsy, four hours after death, the heart was found of very unusual size—nearly as large again as it ought to have been—and both cavities distended with blood, with thrombi formed in them, which extended upwards into the vessel. Death from paralysis of the heart.—American Correspondent of 'Medical Times and Gazette.'

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JULY 13.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, Caledonian road, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, JULY 14.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, JULY 15.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, JULY 16.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

MONDAY, JULY 18.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, JULY 19.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Canada Medical Journal, No. 1.

Weekly Return of the Births and Deaths in the City of Dublin during the Year 1864.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

THE SOCIAL SCIENCE ASSOCIATION.—The notice is inserted.

DR. ROBERT FOWLER'S letter is inserted.

REV. H. BROMFIELD.—The letter is inserted, and the success of the cause has our best wishes.

THE HON. SECRETARIES TO THE LLEWELLYN FUND.—The letter is inserted.

DR. S.—The question is entirely a legal one, and we advise you to consult a solicitor.

MR. H. B., *South Wales.*—The salary is certainly not in proportion to the area, nor to the number of patients attended; and a representation to that effect made to the local Guardians would perhaps lead to redress.

DR. W.—We have no hesitation in expressing our opinion that the conduct described is highly unprofessional, and ought to be represented to the medical men of the district. It is of no use to ask the opinion of the general public, or to expose the matter in the local newspapers.

Total Suppression of the Liquor Traffic and the Wine Trade.—We have received two communications by the same post, one the Manifesto addressed by the Executive of the United Kingdom Alliance to its members and adherents throughout the nation; and, on the other hand, the Annual Circular of a well-known firm of wine-merchants. The former document relates the history of the measures taken to secure the votes of the members of the House of Commons in favour of the so-called Permissive Bill, and speaks in hopeful terms of the probable success of the Bill at some future period; the latter points to statistics, and not only shows that the sale of wines is augmenting, but alleges the fact as indicating the increasing prosperity of the country. The wine circular, besides giving statistics, argues the question with the teetotallers, and recommends them to apply the same principle of total abstinence to every other indulgence, besides that in liquor, which, when carried to excess, may lead to pernicious results; and it defends the judicious employment of stimulants, both as medicines and as means of rational enjoyment to persons living, as most civilised nations do, in an artificial state of society. By this document we also learn that the vintage of sherry last year was below the average in quantity, but that the supply of port was abundant. The consequence is, that sherry is dearer than formerly, while port is not much, if at all, cheaper.

ALPHA.—The letter is inserted.

THE OBSTETRICAL SOCIETY OF LONDON.—The report has been received.

Medical Transfer and Partnership.

30 BUCKLERSBURY, LONDON.

Mr. Orridge, Medical Transfer Agent, Referee, and Valuer of Medical Property, may be consulted, as usual, at the above address.

Office Hours, 11 to 4.

Apothecaries' Hall. — The next EXAMINATION in ARTS will be held at the Hall on Friday and Saturday, the 23rd and 24th September, 1864. A Syllabus of the Subjects for Examination may be had on application.

An Examination will again be held in the month of January, 1865.

R. B. UPTON, Clerk to the Society.

PRIZES IN BOTANY.

The next Examination for the SOCIETY of APOTHECARIES' ANNUAL PRIZES in BOTANY will be held, at the HALL of the SOCIETY, on WEDNESDAY, the 10th of AUGUST next, at 10 a.m.

The Prizes consist of a Gold Medal and a Silver Medal, with a Book. Gentlemen will be eligible as Candidates for such Prizes who shall have commenced the SECOND SUMMER SESSION of their Medical Study.—Candidates must send a written notice to the office of the Beadle, of their intention of competing for the Prizes, on or before the 1st August.

By order of the Court of Assistants,

R. B. UPTON, Clerk to the Society.

Apothecaries' Hall,
July, 1864.

Anatomy, Physiology, Pathology, and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

Liquor Carbonis Detergens, or CONCENTRATED ALCOHOLIC SOLUTION OF THE ACTIVE PRINCIPLES OF COAL TAR.—A new remedy in Cutaneous affections, &c., presenting in an elegant and effective form the several virtues of the Tar, which are held in solution by the Alcohol, and thus rendered applicable to all the purposes of Hygiene, Medicine, and Natural History. As a dressing for putrid sores, where a disinfectant is at the same time desirable, the Emulsion, formed of any required strength by the addition of water, is most readily exhibited, mere agitation producing immediately perfect combination.

Prepared at the Laboratory of WRIGHT, FRANCIS, and CO., Wholesale Druggists, 11, Old Fish street, London, E.C.: and may be obtained through any Chemist.—(Name and Label entered at Stationer's Hall.)

Medical Fixtures and Glass Manufactory, 3 Liverpool street, Bishopsgate, London.

FILMER KIDSTON begs to inform Gentlemen Commencing or Altering in the above Profession, that he has an extensive assortment of HOP and SURGERY FITTINGS, GLASS, EARTHENWARE, &c., of the most improved style and make, on view.—Plans and Estimates furnished. — An assortment of Second-hand Fittings, Bottles, Earthenware, etc. etc.

Bowles and Sons, Label and General PRINTERS, 14 GEORGE STREET, MANSION HOUSE, LONDON, E.C.—Established 1831.

THE MEDICAL PROFESSION, Hospitals, Dispensaries, and large Consumers, supplied by contract or otherwise.—A Catalogue and Pattern-book of Labels, with Samples of Account Notes, &c., free, on application.

Mr. Howard, Surgeon Dentist, 52 FLEET STREET,

has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble natural teeth as not to be distinguished from the original by the closest observer, they will never CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does NOT REQUIRE the EXTRACTION of ROOTS, or any PAINFUL OPERATION, and will support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication. Decayed teeth stopped, and rendered sound and useful in mastication.—52 FLEET STREET. At home from Ten till Five.

Vaccination.—Liquid Vaccine LYMPH, in purity and source guaranteed, in Capillary Glass Tubes, hermetically sealed, which preserves it for any period, supplied to the Profession by Mr. FAULKNER, M.R.C.S., Operative Chemist, &c., Endell street, Long acre, London, W.C. Three Tubes sent by return of post, with instructions, on receipt of 30 stamps.

MAKERS TO THE QUEEN AND PRINCE OF WALES

FRY'S | HOMŒOPATHIC ICELAND MOSS PEARL | COCOA.

FRY'S SOLUBLE CHOCOLATE.

FRY'S CHOCOLATE for Eating in sticks and drops.

The superior quality of J. S. FRY and SONS' Articles has been attested uniform public approbation during a century.

They are the ONLY English house in the trade to whom a PRIZE MEDAL was awarded 1862.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 2.)

The Causes, Diagnosis, and Treatment.

Partial Separation of the Placenta not Morbidly Adherent.—After the birth of the infant, the uterus generally remains quiescent for a short time before it contracts to detach the placenta. Dr. Murphy has given to that condition of the uterus the very appropriate term of "suspended action," in contradistinction to that of true inertia. Now, a not uncommon cause of hæmorrhage is the *partial* detachment of the placenta before the uterus commences to contract. The only safeguards against flooding are either adhesion of the entire placenta, or the uterus empty of its contents and firmly contracted. Both these points are wanting when hæmorrhage occurs from partial separation of the placenta during an uncontracted state of the uterus. The blood flows through the uterus unimpeded, and escapes out of the uterine sinuses corresponding to the detached portion. The afterbirth is so loosely connected to the uterine wall, that very slight disturbances may give rise to its partial detachment—*e. g.*, exertion of the patient, coughing, the application of strong or unequal pressure on the uterus during the absence of contraction, contraction of only a small portion of the uterus, and premature traction on the cord. Then, again, everything that increases the period of suspended action, or produces inertia, will indirectly make a woman liable to flood from the above cause—such as rapid delivery, exhaustion, pulling the infant away after the birth of the head, instead of allowing its expulsion by the uterus, &c.

Diagnosis.—Externally, the uterus is found large and *soft*, and the patient has no afterpains. On internal examination, the interior of the cervix is felt perfectly flaccid; and when the placenta is situated in its normal position, the insertion of the cord will be out of reach. The hæmorrhage comes on generally suddenly, and a large quantity of blood may be lost in a very short space of time; sometimes, almost before we are aware of the existence of the complication, a goodly stream will have wended its way as far as the back of the knee. When there is total absence of uterine contraction, we have no means of ascertaining whether the portion of the placenta still undetached is morbidly adherent or not, until the hand has to be introduced for its removal.

Treatment.—The object to be attained is to make the uterus contract, and detach the whole of the placenta. Apply firm and equable pressure on the uterus with both hands. This simple treatment is, in many cases, quite sufficient; the flooding is at once stayed, and uterine contraction gradually comes on; and on making a vaginal examination, the placenta will be found lying detached at the roof of the vagina. It may be then removed by a continuance of external pressure or by traction. If pressure does not succeed alone, a dose of ergot should be administered, and cold be applied in conjunction with pressure. Dipping the hands in cold water is the best way of applying the two remedies in such cases. If the placenta still keeps attached, and the hæmorrhage continues, no further time ought to be lost; the hand should be introduced, and the placenta removed.

I may here conveniently discuss the question, as to how long we should wait in cases of retained placenta, from whatever cause, before removing it by the hand. That depends a great deal on the absence or existence of hæmorrhage. If the flooding occurs rapidly and to an alarming extent, and firm pressure should not succeed in stopping it in a few minutes, the introduction of the hand should be at once undertaken; if the discharge is more moderate, a longer time may be allowed to elapse, and other remedies tried first—as cold and ergot. In cases where there is no loss, or so little as not to be worth consideration, we may wait half an hour. If the placenta has not separated in that time, no good will be derived by waiting any longer. Some obstetric authorities advise the delay of an hour, and an hour and a half. I am afraid those gentlemen do not preach what they practise; they recommend that delay in their anxiety to prevent inexperienced hands from doing harm; and I doubt very much whether, in their own practice, they find it expedient to wait so long. If we can avoid the introduction of the hand, of course that is a great point gained; but when we fail to detach the placenta in half an hour, we shall, most likely, have to introduce it sooner or later; and for the reasons I shall now mention, the early removal of the placenta by the hand diminishes very much the difficulties of, and objections to, that operation. If the retention of the placenta be due to inertia, it will generally be accompanied by hæmorrhage before the child has been born thirty minutes, from a portion of it becoming detached by the pressure applied externally. I think all will agree with me as to its advisability in cases where flooding is present. There is no remedy which will overcome the inertia so promptly as the peeling off the placenta with the hand. If the cause of the non-detachment be morbid adhesion, it is still more important to remove the placenta early, because, after a time, the uterus, failing to detach and expel it, contracts upon it so firmly, that passing the hand through the os into the uterus becomes no easy matter. After labour the os very rapidly contracts. Another source of difficulty in removing the placenta, when the uterus is firmly contracted, is the limited space the hand has to work in. About three weeks ago, I was called to assist in a case of adherent placenta. The child had been born more than an hour. The first difficulty I experienced was in getting the hand through the contracted os; then the uterus was also so thoroughly contracted, that the hand completely occupied its cavity. I was some time before I succeeded in detaching the whole of the placenta, on account of the movements of the fingers being so seriously interfered with. About an hour ago, I was asked to assist in a case of twins. The first child had been born an hour. The second was breech presentation, and its delivery was pretty readily effected. About five minutes after, uterine contraction recommenced, and recurred several times in the course of half an hour. The uterus externally was large and hard. The vaginal examination proved that the placentæ were not detached; and as there was no hæmorrhage, it was pretty clear that they were not even partially separated. On passing my hand into the uterus, I found the two placentæ covered a very large space, from the fundus to within an inch of the os, and they were entirely adherent. If I had allowed an hour to elapse before attempting their removal, I should have met with the same difficulties as in the first case, for even in half an hour the uterus had contracted pretty firmly.

The operation causes less suffering when it is performed in the first than in the second half-hour. The pressure of the head on the soft parts in its passage through the pelvis has so numbed their sensibility, that, if the hand is passed into the uterus immediately after delivery, it gives rise to little or no pain. The sensitiveness of the vagina and vulva gradually returns. When I come to speak of irregular or hour-glass contraction, I hope to show that the early removal of the placenta may in some cases prevent that undesirable complication. The detachment of the placenta is very easily effected if its retention is due only to suspended action, or inertia of the uterus. The portion of the placenta which has become detached should be searched for, and the fingers placed between it and the uterus; the rest may be then separated by a combined forward and side-to-side movement of the fingers. The uterus must be steadied outside by the right hand of the operator, passed between the thighs of the patient. The hand and the placenta should not be removed until we are

certain that the whole has been detached, and that contraction of the uterus has set in.

In illustration of hæmorrhage produced by partial detachment of the placenta during the suspended action of the uterus, I shall give notes of two cases :—

1. A. R., æt. twenty-two, primipara, was delivered of a male infant after a labour of ten hours. I had but just separated the child from the mother when severe flooding set in. For a short time the blood issued from the vulva like water from a pump. The uterus externally was large and soft ; and on internal examination, the funis was felt passing through the os, its insertion being quite out of reach. I applied strong and continued pressure with both hands over the fundus and sides of the uterus ; a good contraction very soon followed ; and on making another examination, a portion of the placenta was felt protruding into the vagina. It was then removed, partly by external pressure and partly by traction. The uterus contracted firmly, and no further hæmorrhage occurred.

2. The following case I briefly referred to before, in Precaution 17. I was called to attend this woman in her second labour, at eleven p.m. The head was presenting, and the os was the size of a florin. About half an hour after, I was obliged to leave her to go and attend another case. At a quarter-past one, her husband came to say that the child was born, and hoped I would come immediately. I could not at that moment leave the second patient, as the placenta was not delivered. Shortly after, the husband came again, and said I must go with him, as he thought his wife was dying. On entering the patient's room, I first thought she was dead. There was not a vestige of colour in her face or lips, her eyes were closed, and she lay perfectly motionless. I spoke to her and asked how she felt. She very faintly whispered, "I feel so faint ; I can't see." On examining the uterus, I found it as large as if she had not been delivered at all. The first thing I naturally asked for was brandy, and the mother of the patient handed me over a bottle containing about an ounce and a half, at the same time saying that was all they had in the house. This information staggered me, for it being then the middle of the night, I knew no more brandy could be obtained without great difficulty. It seemed to me impossible that this small quantity of brandy would prove sufficient to rally the patient ; not only was she in a most dangerous state of depression from loss of blood, but the very remedy I should have to employ, in order to stop the hæmorrhage, would tend for a time to increase the shock. However, it was no use standing looking at the patient—something must be done. The husband was sent out immediately to get some more brandy. I then rapidly discussed in my mind as to which one of two modes of treatment I should follow in this case. Would it be better first to rally the patient, and wait until more brandy could be obtained before proceeding to remove the placenta and clots ; or had I better at once remove the contents of the uterus, and rally her at the same time ? The first plan was uncertain : I might have rallied the patient, but it would have been only temporary ; and if I could not have got any more brandy in a short time, which was very likely, I should have had to remove the placenta and clots without any means of counteracting the shock of the operation. I determined at once to remove the uterine contents and to order the nurse to make the patient drink the brandy neat at the same time. About half of the placenta was still attached ; on its removal, with a large quantity of clots, the uterus contracted firmly to the size of a man's fist, and the hæmorrhage fortunately was at once arrested. By this means, I killed two birds with one stone ; the patient was rallied, and the flooding stopped. It turned out, after all, that I had to leave the patient in order to find a policeman to assist me in getting more brandy. The patient was in a very dangerous state for several hours, fainting away every few minutes ; but she ultimately recovered.

There is another plan of treatment which some might ask why I did not try. Why did I not attempt to expel the placenta and clots by external pressure ? Because, when the uterus is so distended, as it was in the above case, even if I had succeeded in expelling the contents by pressure, as much depression would have followed. It was most probable, however, that this means would only have been partially successful ; it might have expelled some of the clots, but not have entirely emptied the uterus. In that case, the patient would have been disturbed without any good resulting ; a fresh attack of hæmorrhage might have been brought on ; time would have been lost, and the introduction of the hand required after all. In a case where the patient is hanging between life and death, trifling remedies are almost as bad as none.

HOSPITAL REPORTS.

KING'S COLLEGE.

DISEASES OF THE FEMUR.

(Continued from page 20.)

Treatment of Femoral Coxalgia.—We have seen that the symptoms of this disease are, in the early stages, indicative of an inflammatory character of action, and we must be guided in our treatment accordingly.

Absolute rest must be enjoined and strictly enforced ; in order, therefore, to secure it for the limb, we must have recourse to a leather or to a gutta-percha splint, or to the starched bandage ; in one or other of these appliances, the pelvis, thigh, and leg had better be encased soon after the invasion of the disease. While rest is being thus gained, we must, as a local measure of treatment, use counter-irritation ; and this may at first be accomplished by means of blisters either to the sacrum or to the thigh—posteriorly, behind and over the trochanter major, or, in front, over the site of the pectinæus. The blistered surfaces should then be kept open for some time, till decided benefit was obtained from the application of the blisters. If, however, we should not wish to produce vesication, but merely counter-irritative action, we can apply a number of blisters in rapid succession ; and leaving them on only for a short time, we can effect that amount of irritation which we seek to obtain.

Should we not wish to use fly-blisters we might paint the surface to be blistered with a strong solution of iodine and iodide of potassium in spirits, and then over it lay a piece of lint of a size equal to the extent of surface which we intend to vesicate ; the lint should then be saturated with the iodine solution and have placed over it, to prevent evaporation of the solution, a piece of oil-silk or gutta-percha paper, or, what is perhaps better, a watch-glass, which, being pressed tightly down upon the integuments, effectually prevents all evaporation. Instead of the iodine solution, we may use the strong liquor of ammonia. There is an objection, however, urged against vesicating by means of this last agency ; it is, that the vesicant action is too rapid, and that it is not, therefore, able to withdraw the blood from the interior to the surface, nor to subdue inflammatory processes, nor procure an alterative condition in the joint.

When we apply in rapid succession a number of vesicating agents, our object is, not to procure a blistered condition of the integument, but the greatest amount of irritation short of such a condition ; and this will be found more efficacious than raising the outer from the inner skin by creating an effusion of serum between them ; especially as it can be often repeated, owing to the outer skin not being stripped from off the subjacent tissues and there being consequently no exposure of the sensitive true skin.

If we blister the integument, we must wait till the wound so formed heals, before we can again apply another vesicant ; and the healing process progresses so slowly and takes so long a time to be completed, that the beneficial effects of the first blister will in a certain measure have subsided or passed off, before we can apply a second.

Instead of using such remedial agents, we may have recourse to issues placed either in front over the pectinæus muscle, or behind, in a situation posterior to the great trochanter of the femur. We may make an issue by pinching up the integument in our fingers, then slitting it with a lancet, and in the slit or slits inserting a number of peas, which will prevent the healing of the wound, and will,

moreover, create and keep up a constant drain from the part, in the shape of a purulent or sero-purulent discharge. Another method of making an issue is by means of "firing" the skin in the neighbourhood of the diseased joint, and, afterwards, when each spot so burnt becomes converted into a superficial ulcer, maintaining a discharge by the aid of stimulating dressings.

The best instrument for this firing process is that devised by Dr. Corrigan, of Dublin, and which is known in the Irish schools of medicine by the name of its inventor. It is a small-sized instrument, but can of course be made of any size to suit the wishes of the surgeon; the handle is enclosed in a wooden case, so that the hand of the operator can grasp it when the other extremity of the instrument is heated. The terminal end of the instrument is expanded and somewhat button-shaped, and when it is to be applied to the integument is heated in the flame of a spirit-lamp. The degree of heat is regulated by the forefinger of the hand in which the instrument is retained; the finger being placed on the centre of the body of the instrument, and kept there till the increasing heat occasions positive pain, or till that amount of caloric is generated in the instrument which the operator may consider sufficient for his purpose.

The caustic issue is obtained by the following processes:—A piece of adhesive plaster is folded upon itself several times, so that a number of layers are placed the one over the other; and each adhering to the other, there is formed a firm and certain protective agent to the integument, and which will be found to resist the burning properties of the caustic. In the centre of this shield of adhesive plaster an aperture is made, but of a size smaller than the circumference of the area which we intend the issue should occupy. Were the aperture not thus made smaller than we intend the issue itself to be, the caustic, spreading itself for some little distance beyond the circle of the aperture, would form an ulcer larger than we originally intended, and perhaps so large as to be a source of constant annoyance to the patient, and a too great drain upon the system.

The plaster, with the aperture in it, being put upon the spot where we wish to make the issue, the potassa fusa—for it is the caustic to be used—is rubbed freely over the circle of skin included in the aperture of the plaster, or, if the potassa be made into a paste with the aid of black soap—equal parts of each being employed—the paste should be laid upon the integument, which appears in the circular aperture of the plaster, and should be allowed to remain until the skin be reduced to a sloughy mass. As soon as this condition is produced, a poultice must be applied, and must be regularly renewed, till the slough comes away, when a number of peas must be placed in the wound to insure its being kept open.

The issue should have a healthy appearance, and the discharge issuing from it should have a similarly healthy character; otherwise the issue has a detrimental rather than an improving effect.

Another method of producing counter-irritation, or vesication, or even cauteration, is that by means of the moxa. This had its origination in the East, whence it was introduced amongst us, but without ever coming into very general use. The moxa itself may be made from the fibres of any of the various forms of porous vegetables, from linen, or from cotton saturated with nitre; or from a substance known as German tinder. It should be placed on the spot which we wish to be affected by it, and, when surrounded with wetted pieces of rag, it should be ignited, and made to burn down to the integument till the latter is reduced to an eschar.

The moxa as used amongst the Chinese is obtained from the leaves of the *Artemisia moxa*, a shrub indigenous to China, and a member of the natural family Compositæ (Asteraceæ), and of the Linnæan class and order *Syngenesia superflua*.

The plan adopted for its preparation from the Artemisia is that, by the removing of the down from the leaves of the shrub, and then pounding it into a substance like cotton: when this is done, the cotton-like substance is rolled into balls of a conical shape, and set aside for use.

The late Professor Osborne, of Dublin, proposed, and was in the habit of using, the freshly-burned quicklime instead of any other material from which the moxa could be prepared.

The uneasiness, but yet not disagreeable sensation, which at first the moxa produces on that part of the skin where it rests is quickly succeeded by distress and actual pain; these are not, however, of long continuance, as the moxa burning down quickly causes rapid inflammation and destruction of the subjacent parts, so that they are speedily reduced to a black slough, which separates itself from the living tissues in a week or a fortnight, or in any time intermediate.

The effect of the moxa is essentially a slow process, and the inflammatory action induced by it extends so very deeply, that the benefit derived from it can be of no inconsiderable moment.

The treatment should be as follows:—Rest, absolute and perfect, and to be obtained in the manner we have previously mentioned; a succession of counter-irritant applications, or of blisters; an establishing of a discharge, by means of issues, or the moxa; an alterative course of medicine in the commencement; the hydrarg. cum cretâ, with rhubarb and some potash or soda salt, will be found to be very efficacious. The strength should be improved and supported by the best and most nutritious diet, taking care, however, to suit the food to the age of the patient, and to the condition of debility both of the stomach and of the constitution generally, neither so to load the stomach as to hinder digestion, nor to allow a surfeit of food, lest the system be disturbed and feverishness or positive fever be induced, which will thwart our efforts by increasing the patient's debility, and consequently his powers of resisting the progress of the constitutional taint, or of the local disease of which it is the development, and of which it is symptomatic.

Quinine and the muriate tincture of iron may be prescribed, both in the case of children and adults; to the latter we may likewise administer the bichloride of mercury with some preparation of cinchona, or else in, as a vehicle, the compound decoction of sarsaparilla.

Later in the course of our treatment, we must order cod-liver oil, the iodide of potassium, or, for children and females, especially if they be of a delicate habit, the syrup of the iodide of iron, which is an excellent combination of the two metals, and is both an agreeable tonic and a valuable alterative, as well as possessed of directly anti-strumous properties.

The bowels should be kept in healthy action, and, to promote this end, their secretions, especially the biliary, should claim no small attention. Very frequently feverishness is induced by the irregular state of the bowels.

When the joint is in a condition to allow the patient to move about, it is most advisable that he should be transferred to the sea-side, where he may enjoy the benefit of sea-air and sea-bathing.

If we cannot effect a complete cure of the diseased joint, our object should then be to procure anchylosis. When this is accomplished, the patient will yet have excellent use of the limb, because the pelvis and entire extremity will get an increase in mobility dependent upon increased powers of motion in the lower vertebræ.

The condition of the skin should not all through our treatment be overlooked, since it is of importance that it should be kept in as complete action as possible. For this purpose, it may be sponged either daily or every other day with some tepid water-and-vinegar, and then rubbed with a coarse towel or with a flesh-brush, till redness and a glow of heat be educed.

The consequences or sequelæ of femoral coxalgia (some of which we have already mentioned) are:—Anchylosis: this may be very faulty as to the manner in which it alters the position of the limb, flexing it upon the abdomen, inverting and adducting it, shortening it either by an actual displacement or dislocation of the head of the femur, or by a mere elevation of the pelvis on the diseased side. Besides these deviations from its natural position, the limb is sometimes twisted over that of the opposite side.

These errors of anchylosis may all be corrected while the patient is under the influence of chloroform, and the limb can be made to resume almost, if not quite, altogether, its wonted position.

Another of the sequelæ is dislocation of the head of the femur from its socket in the acetabulum to the dorsum ilii. This is the occasion of the shortening. When such a condition supervenes, a false joint will in many instances be created on the dorsum, and in it the head of the bone will come to lie. The cavity, in which the head of the bone rests, may sometimes be so imperfect as to be unworthy the name of even a "false-joint;" and this occurs especially when there has been extensive suppuration, the formation of several abscesses, and, synchronously, a carious state of the dislodged head of the femur.

Dislocation is often attended with, or preceded by, collections of matter, and the resolving of such collections into abscesses; the situations in which these abscesses determine we have indicated in a former part of this paper.

The causes of the head of the bone passing from its natural situation are—First, an alteration and degeneration in the tissue of the bone. The degeneration consists in a reduction of the healthy osseous substance to a carious state, whereby the bone can be and is readily absorbed, and in some cases so much so, that the cotyloid cavity is left unfilled. At the same time that these changes are occurring in the osseous structures, the ligamentous will be found to be implicated in the disease, being either partially or totally destroyed, so that there is a very imperfect retaining force, or, perhaps, none at all affixed to the head of the femur; and hence the facility with which it becomes dislodged.

The second cause of displacement of the head of the femur is destruction of the capsular ligament and of the ligamentum teres as a result of inflammation. There may be no, or almost no, bone disease; the head of the femur may, notwithstanding, be resting upon the dorsum ilii, where it has been thrown by the action of the powerful muscles of the thigh and hip.

A third cause of the femoral dislodgment is a growing-up from the bottom and a filling-in of the cotyloid cavity, so that the head of the bone is in fact pushed from its natural position, and then drawn upon the dorsum by the force of muscular action.

The next consequence of femoral hip-disease to which we shall advert is the formation of matter and the resolution of such collections of matter into abscesses, which in a great number of cases are followed by sinuses that are in themselves most difficult to heal, not alone on account of their actual want of vitalising power, but likewise because of the low state of the constitution generally.

The suppurative processes usually take place in the strumous subjects of the disease, and more especially in those whose health has become debilitated. They occur early in the affection.

The site of the abscesses is generally at first behind the joint, and deeply situated amongst the glutei muscles; but from these places the abscesses travel forwards or downwards, or inwards—that is, towards the inside of the thigh. Sometimes they originate anteriorly in front of the joint, and immediately underneath the pectinæus muscle; in this situation they occasion a no small amount of pain, owing to the pressure they exercise upon the obturator nerve or its branches.

PARISIAN MEDICAL NEWS.

PROGRESS OF SUICIDE IN EUROPE.

The causes of suicide have at all times engaged a large share of the attention of moral philosophers, and we therefore feel no surprise that so eminent an inquirer as M. Legoyt, the head clerk of the Statistical Office at the Ministry of Agriculture and Public Works, should have taken advantage of his important situation to inquire into the circumstances which contribute to the gradual increase of suicide in Europe.

M. Legoyt, a candidate for the seat of free resident member of the Academy, read a paper, in which he establishes the fact that in Bavaria, Denmark, France, Hanover, Mecklenburg, Prussia, Saxony, and Sweden, the statistical returns of cases of suicide betray a more rapid increase than the population, and the figures of general mortality.

Suicide is especially frequent in Northern Germany and in the different parts of Denmark; Sweden and Norway, although inhabited by a population closely allied with that of Denmark, present far more favourable returns. With regard to the frequency of suicide, England, despite the popular prejudice entertained on the subject, is the country in which the crime is least common. Self-destruction rarely occurs in Belgium, Austria, and Spain; France occupies an intermediate rank, and might be classed with the three last-named countries, were it possible to set aside the suicides which occur in Paris, and form the seventh part of those supplied by the whole of the French Empire.

M. Legoyt stated that the amount of females who commit suicide is 30 per cent. only, that the frequency of self-murder is in direct proportion to age, that the smallest number occurs in January and the largest in July, and that married persons attempt the crime less frequently than the unmarried, and much less than widowers. One class of persons, however, supplies a longer list of suicides than any other—viz., those who have been divorced or separated.

The most important point established by M. Legoyt's inquiry is the general and rapid increase of suicide. The author ascribes this melancholy fact to the excessive competition encouraged in every trade, art, and profession, to the universal spreading taste for luxury, to political excitement and unlimited speculation; these causes, all inherent in a highly developed state of civilisation, are more easily pointed out than removed.—'Journal of Practical Medicine and Surgery.'

EXCISION OF THE KNEE.

The Dublin Chirurgical Society and the Société de Chirurgie of Paris have both recently discussed the question of excision of the knee-joint. Mr. Butcher has four times performed the operation, but he remarks that ultimate success depends upon the excessive care bestowed upon the patient, and that the procedure should be attempted under the most favourable circumstances only, and when it is possible to watch the patient with very minute attention.

This view is fully confirmed by the recent returns of American Army Surgeons. Indeed, the 'Revue des Médecins d'Armée informs us that the constantly fatal results of excision of the knee-joint, after the battles of Antietam and Fredericksburg, have caused the operation to be set aside altogether.

M. Verneuil has twice resorted to the procedure with entire success in cases of gun-shot wounds, and thinks himself justified in again inviting the attention of Military Surgeons to excision of the knee. M. Verneuil is, doubtless, indebted to his great skill and experience for his good fortune; but MM. Larrey and Legouest showed that, on the field of battle, the operation is well-nigh impracticable and that, for the present, at least, it cannot be generally applied in a campaign.

M. Velpeau believes that in private practice it will not gain more permanent favour—"not," said the Professor, "on account of any difficulty in its performance, but because it is a more painful, a longer and a more dangerous operation than amputation, both as to its immediate and secondary sequelæ; and more especially, because, in the most successful cases, the preserved limb is rarely less serviceable than an artificial one—a joint cannot be restored, the movements remain very confined and imperfect, and the foot is always much deviated outwards." If, therefore, M. Velpeau's assertion is true, that excision of the knee-joint is frequently fatal, and if, on the other hand, the extremity preserved is less useful than a wooden leg, surgeons will be indisposed to share in M. Verneuil's predilection for a procedure which foreign statistics would seem to have pre-

sented to us in too favourable a light.—'Journal of Practical Medicine and Surgery.'

CURE OF TRAUMATIC TETANUS.

M. Mascarel, a corresponding member of the Society of Surgery, communicated, on the 25th of May, some interesting particulars on a case of traumatic tetanus in which a cure was affected. The patient was an inspector of musketry, who received a gun-shot wound in the lower part of the thigh. Cold irrigations were instituted at once; the injury was inflicted in the month of September, while the weather was still very warm. Trismus soon supervened, and despite the exhibition of a grain of opium every hour, the convulsive action rapidly invaded every part of the body. Two grains of opium were then administered every hour, and the wound was repeatedly dressed with compresses impregnated with a strong decoction of belladonna leaves. In the course of twenty-four hours the spasmodically contracted muscles began to relax, but at the same time vomiting and other symptoms indicative of the absorption of the opium and belladonna set in, and the treatment was discontinued. The tetanic convulsion subsided altogether and a complete cure was effected after an interval of four months, during which a large number of splinters of bone escaped from the wound.

M. Marjolin remarked that in tetanus he had found much benefit from the sudorific method recommended by Dietch. The patient, entirely undressed, is wrapped in a woollen blanket, and warm drinks containing a small quantity of the liquor ammon. acetatis are frequently administered. Copious perspiration follows, and in a short time a remission is observed in the morbid spasmodic action.

In another part of the present number, we report a case of idiopathic tetanus in which the symptoms were allayed by this method, combined with the use of the Calabar bean.—'Journal of Practical Medicine and Surgery.'

REVIEW OF BOOKS.

Stimulants and Narcotics: their Mutual Relations; with Special Researches on the Action of Alcohol, Æther, and Chloroform, on the Vital Organism. By Francis E. Anstie, M.D., M.R.C.P., Assistant-Physician to Westminster Hospital, &c. Pp. 489. Macmillan and Co. 1864.

Recent experiments upon the lower animals, and observations made upon the human subject, both in health and disease, have induced many modern physiologists to doubt altogether the truth of the doctrines long entertained on the subject of muscular and nervous action, and on the operation of certain external agents, whether nutritive or medicinal, chemical or mechanical, upon the living organism. In fact, it would appear that we ought not only to question the accuracy of certain received opinions on these subjects, but to reverse altogether the propositions which have hitherto been advanced. A muscle was formerly supposed to contract in consequence of the application of some stimulating agent, and to relax when the stimulation was withdrawn; but now it seems nearer to the truth to believe that the contracted state of muscle is due to the want of stimulus, and its relaxation to the opposite condition. The muscles contract after death, because the stimulus of life is withdrawn; and the irregular and violent contraction of muscles during life is due to deficient, not to excessive, vital energy. In our notice of Dr. Radcliffe's 'Lectures on Epilepsy, Pain, and Paralysis,' a week or two since, we noticed some of the evidence on which these new opinions rested; and we may state that Dr. Anstie supports Dr. Radcliffe's conclusions.

The title of Dr. Anstie's work conveys, though somewhat imperfectly, the nature of the subjects discussed in his pages, which are devoted to an historical and critical disquisition of the existing doctrines of stimulus and narcosis, a reconstruction of our views as to the use of these terms, and a number of practical researches upon the effects produced by alcohol, ether, and chloroform.

"The existing doctrine of stimulus assumes that all mental excitement, all increased sensibility and pain, all convulsive muscular action, all considerable increase of secretion, and all increase, whether of force or frequency of the heart's action, are caused by, and are the proofs of, a stimulant action upon the organism." These are the doctrines which Dr. Anstie places before us, and which he proceeds to demolish, though in some respects his reasoning is more ingenious than conclusive, and in others he labours very earnestly to prove what is already very generally admitted. Thus, in the case of mental excitement, he argues that the early phenomena of alcoholic intoxication are not really referable to excitement, but to the reverse condition; and that although the emotional and appetitive parts of the mind are in action, the intellect is directly enfeebled. His theory seems to be that, in the ordinary state of the mind, the intellect is in a state of excitement, in its continual effort to restrain and control the wanderings of the fancy or the play of the emotions; while, on the other hand, the effect of alcohol is to depress the powers of the intellect, and thus diminish its efficacy in restraint. This view is novel and ingenious, though certainly paradoxical; but his remarks on the phenomena of sensation are for the most part by no means new, inasmuch as they have long been anticipated by most practical professors of the healing art. He takes considerable pains to prove that neuralgia is caused by deficiency, and not by excess of vital action, and ought, therefore, to be treated by remedies which restore strength, and not by measures which have the opposite tendency. In this recommendation he will have no opponents, though his subsequent observations on inflammatory pain, which he refers to the same category as neuralgic pain, will not, perhaps, meet with such general acceptance, although we ourselves are by no means indisposed to admit, on theoretical grounds, that inflammation is a sign of diminished rather than of exalted vital force. In his views of muscular contraction, in reference to epilepsy and epileptiform diseases, he follows Dr. Radcliffe, and deprecates depletory measures, in which course, again, he will meet with general concurrence; and in reference to the heart, he argues that increased rapidity of its action is often caused by weakness of the organ, or of the constitution—a proposition which is quite incontrovertible.

Dr. Anstie proposes, therefore, to modify or reconstruct the existing doctrine of stimulus; and while retaining the name, he recommends that it should be used to signify, not that excess of vital force which is at present implied by stimulation, but the relief of pain, the removal of muscular spasm, tremor, or convulsion, the reduction of undue frequency of the circulation, the reduction of excessive secretion, the removal of general debility or of special fatigue of some organs, the removal of delirium or maniacal excitement, and the production of healthy sleep, the support of the organism in the absence of ordinary food, and the local increase of nutrition when the nutrition is deficient.

In discussing the question of the distinction between stimulants and narcotics, Dr. Anstie endeavours to prove that there is no inherent difference, but that stimulants and narcotics may be interchangeable terms, the effect depending upon the relative quantity employed. Thus, in the case of the three well-known agents—alcohol, ether, and chloroform—on which Dr. Anstie offers the results of his special researches, each of these substances may be stimulant or narcotic, according to the dose which is employed; and opium possesses the same peculiarity. Hashish, made from Indian hemp, and coca (a Peruvian narcotico-stimulant, from the *Erythroxylon coca*) are used in very large quantities in certain parts of the world, and also possess different properties in proportion to the dose. In reference to the use of these and similar agents, it is remarked as a peculiar fact, that nearly all mankind employ some article, either natural or manufactured, for the purpose of exhilaration or stupefaction—such as opium, tobacco, alcohol, coca, hashish, &c.—and that the moderate use of these substances is attended only by stimulus in the favourable sense in which the word is used by Dr. Anstie. When used immoderately, and only then, narcotic and poisonous effects are produced.

It will readily be understood that Dr. Anstie defends the use of these substances within moderate limits, and that he by no means endorses the views of those who consider alcohol and tobacco to be poisons; he even extends his defence to opium, which he believes to be employed with benefit as a luxury, or rather as a wholesome stimulus, in Oriental countries. He considers alcohol, as used in civilised countries, to be a useful and necessary article of diet; and, brought up in the Medical School of King's College and admiring the views of the late Dr. Todd, he places great faith in its use as a remedy in disease. He thinks that the physiological question as to the exact change which alcohol undergoes in the system has not yet been settled, but he has no doubt that it may often take the place of food; and he gives several striking instances in support of this opinion.

From the above hasty sketch of Dr. Anstie's book, it will be perceived that it comprehends the discussion of a great number of interesting subjects, and that the author treads on much debatable ground. But we have read the work with great pleasure; and although we are not prepared to agree with Dr. Anstie in all his conclusions, we can bestow unqualified commendation upon the learning and ability he has brought to his task, and upon the suggestive and original style in which he has treated some of the most important questions in physiology and practical Medicine.

The Half-Yearly Abstract of the Medical Sciences. Edited by W. H. Ranking, M.D. Cantab., and C. B. Radcliffe, M.D. Lond., Vol. XXXIX. January to June, 1864. London: Churchill and Sons.

The present volume of this abstract contains, as usual, a very able *résumé* of the progress of Medicine, Surgery, and Midwifery during the last half-year; and the editors appear to have availed themselves of all accessible means of information on these subjects. The volume is got up in the same careful style which has always characterised it, and a few woodcuts are introduced where they are necessary for the elucidation of the text. The report on the Progress of the Medical Sciences is limited to a report on Materia Medica and Therapeutics, and most of the books lately published on that subject are briefly but fairly analysed and commented upon.

Selecta è Præscriptis. Selections from Physicians' Prescriptions, containing Lists of the Terms, Phrases, Contractions, and Abbreviations used in Prescriptions, with Explanatory Notes: the Grammatical Construction of Prescriptions; Rules for the Pronunciation of Pharmaceutical Terms; a Prosodiacal Vocabulary of the Names of Drugs, &c.; and a Series of Abbreviated Prescriptions, illustrating the use of the Preceding Terms, &c. By Jonathan Pereira, M.D., F.R.S. Fourteenth Edition. Pp. 352. London: Churchill and Sons. 1864.

Among the earliest, if it was not the earliest, of the late Dr. Pereira's works was the 'Selecta è Præscriptis,' a little volume which has probably not only helped many a medical aspirant over the *pons asinorum* of Latinity required at some of the Examining Boards, but has also been of some essential service to many practitioners in their daily medical and surgical ministrations. The contents of the book show in a very well-marked manner that facility of description, abundance of illustration, and terseness of style, which distinguished Dr. Pereira's subsequent and larger works; but after the numerous editions which the 'Selecta è Prescriptis' has passed through, we feel that it is unnecessary to expatiate upon its merits, or to do more than to announce the present issue, and to state that it has been brought up in all respects to the standard of the present day.

SIR WILLIAM WILDE.—This distinguished surgeon has lately received an honorary Degree in Medicine from the University of Dublin.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Professor FERGUSSON'S sixth and last lecture "On the Progress of Anatomy and Surgery during the Present Century" commences the number. We give an abstract of this discourse in another part of our Journal.——SIR J. RANALD MARTIN contributes a valuable paper "On Hepatic Diseases in the East Indies," especially Hepatitis, his remarks being founded on his own long experience in the East. He describes two forms of hepatitis—one in which the serous covering of the liver is inflamed, and which is characterised by great pain, with difficulty of breathing and cough, if the upper surface is affected, and hiccup, nausea, and vomiting, when the disease is chiefly seated in the lower or concave surface; and another far more severe and dangerous form of hepatitis, where the parenchyma of the organ is inflamed. In this latter form of the disease the pain is much less, and the symptoms altogether are more insidious; but the formation of abscess speedily ensues, attended very often with a fatal result. Sir Ranald Martin strongly urges the adoption of prompt and energetic measures in the treatment of this affection; and without regarding the theoretical views of some writers (chiefly European, and who have not seen the disease in tropical countries), he advises general blood-letting and the use of calomel, and when the acute symptoms have subsided, the persevering administration of the nitro-muriatic acid internally, and its application externally, in the form of baths, both general and local.——Dr. JAMES A. SEWELL communicates a paper "On the Use of Tea as a Remedy in Coma," and he relates several instances in which the administration of this herb has been attended with the most beneficial effects. In one case in particular, a person had swallowed, for the relief of some spasmodic affection, the enormous quantity of two ounces and a half of Battley's sedative solution; in about eight hours she became comatose, was unable to swallow, and appeared to be sinking so fast that the stomach-pump could not safely be employed. Dr. Sewell, therefore, recommended the injection of a pint of the strongest possible infusion of green tea by the rectum, and he believes that the successful result was fairly attributable to this treatment.

THE 'MEDICAL TIMES AND GAZETTE.'

We have now to pass in review the sixth lecture of Professor Fergusson on the subject of "The Progress of Surgery during the Present Century." The lecture opens with a reference to the fact noted by Dr. Humphry, of Cambridge, and by Mr. Pemberton, of Birmingham, that, when the joint is excised in those who have not done growing, the limb so operated on becomes, after a time, shorter than the other, not only by the length removed, but also by an actual arrest in its growth, and that this shortening may sometimes be so much as nine inches. Dr. Humphry has pointed out that the long bones—and of these the femur especially—grow for the most part from their cartilaginous or epiphysal extremities, but especially from their lower ends; if, therefore, the femur be deprived of that part of

itself where growth takes place most quickly, or nearly almost altogether, it cannot grow in the same ratio as the bone of the opposite side. This is a ground of objection to the operation in the young subject; moreover, in such cases, the anchylosis after the operation is not always of a firm osseous nature, as was demonstrated in two subjects, of whom one was a patient of Mr. Pemberton, and the other of Dr. Keith, of Aberdeen. Professor Fergusson considers the hazard to life to be less in the case of excision of the knee-joint than in that of amputation of the thigh, and that excision of the elbow is not at all a safer operative procedure than is amputation above that joint, though in either instance a fatal result is infrequent. The evils—and their name is legion—attendant upon amputation should be sufficient to deter the surgeon from such a measure, unless it cannot possibly be avoided, or unless the condition of the parts requiring surgical interference is of such a character as to preclude the idea of excision of the joint. So much of a limb is retained and preserved for use to the patient when mere excision is practised, that it is a positive absurdity to compare this method of operation with that of amputation: in one case an artificial leg has to be worn, while in the other the natural limb is allowed to remain. In distortion after knee-joint disease amputation instead of excision is wholly unwarrantable, except in some very particular cases. A shortened limb, even though diminished in length to the extent of nine inches, is far better than none at all. Such is the reasoning of Mr. Fergusson. A stump is characterised as "barely little more than a peg whereon to hang an artificial limb." Shortening can be obviated by the wearing of a high-soled boot or shoe. A stump does not improve with time; while the converse holds good in the case of a limb in which excision has been performed, the thigh, leg, and foot becoming increased in their muscular power and vigour, the calf of the leg being especially well developed. The very great value of the feet, as shown in the history of the famous gymnast, Harvey Leech, is dwelt upon at some length in order clearly to demonstrate the loss sustained by the economy in the removal of such members, when they are at all capable of performing their offices. Professor Fergusson adheres to his original opinion that excision of the knee-joint is perfectly justifiable in the growing patient, even though the consequence may be an arrest in the growth of the leg as regards its length; and this opinion he rests on the fact that the leg left to the patient after such an operation is far preferable to any stump, no matter how good it may be. A case illustrative of the benefit gained by even a second incision, where the first had failed to effect the object sought to be obtained, is brought forward, and this is stated to be a preferable mode of treatment to amputation as a secondary alternative. Cases in which the knee is bent and the entire limb shortened, flaccid, and so useless that the patient is forced to use a crutch, may regain a valuable limb by the removal of the stiffened or anchylosed ends of the bone, by then straightening the leg and treating it in the same manner as we should adopt had compound fracture been the lesion. This kind of operation had been carried out by Mr. Price, and was decidedly a better remedial measure than the removal of a wedge-shaped piece from the head of the tibia, as recommended by Mr. Burton. In one instance Mr. Fergusson has performed excision of the knee three times, and with most excellent result.——Under the head of "Original Communications," Mr. BARRON, of the Isle of Wight Infirmary, contributes "A Case of Large Fatty Tumour removed from the Buttock." The patient was in delicate health at the time of operation, and the tumour measured before the operation thirty-six inches in circumference, and twenty-two in its greatest diameter, which was from above downwards; the weight was 30lbs. The operation had been resorted to at the earnest entreaties of the patient, who, in the commencement of the disease, had strenuously refused all surgical aid. The tumour had taken six years to attain its present size, and had of late years taken on a rapid growth. It was semicircular in shape; in some places it was elastic; in others it gave, when tapped with the fingers, the sensation as of fluid contents, though none escaped when a trochar was introduced. The tumour was excised; only six ounces of blood were lost. The wound had a healthy aspect; the patient woke to consciousness very soon after the completion of the operation, but only to sink rapidly from debility, aggravated by incessant vomiting.——A "Case of Cystin-Calculus" is communicated by Dr. WARNCKE, for the translation of which the Journal is indebted to Dr. Moore, of Dublin. The calculus lay in a pouch in the bladder and had been removed by Professor Buntzen; its weight is nearly 600 gr.; in size it is about that of a small hen's-egg, and measures $1\frac{3}{4}$ inches in length, and 1 inch and 5 lines in breadth; it is uneven on its surface, which is likewise of a dull yellow glistening appearance; its section is smooth, greasy, and laminated.

INCREASE OF INSANITY.—The following facts appear in the annual report of the Commissioners in Lunacy to the Lord Chancellor, which has just been published. These gentlemen state that in January, 1849, the number of insane in our asylums amounted to 14,560, and in January last they had risen to 28,285. Fifteen years ago there were in asylums of every description 10,801 paupers, whereas we have now as many as 22,958 belonging to this class. The singular disproportion between the sexes in pauper and private patients deserves notice. Three years ago the women exceeded the men in the pauper class, and in the private just the reverse. According to the last return, in the pauper class the number of women exceeded that of the men by 2,000. In the private class the number of men exceeded that of the women by 795; whereas, in 1849, the number of females exceeded that of the males in this class. The explanation of this circumstance was due to the introduction in former returns of several classes of male patients not previously included—as, for instance, those belonging to the army and navy. Another very important and remarkable statement, as showing the public estimation of private and public asylums respectively, is exhibited in the fact that fifteen years ago there were in licensed houses nearly as many patients as in hospitals and county asylums; whereas we now find that in the latter there are more than five times as many patients as in the former. On January 1, 1849, there were 6,931 patients in private asylums and 7,269 in public. In the former there are now only 4,455, and in the latter as many as 23,830. The Commissioners in Lunacy exercise a watchful care over the welfare of 44,695 persons of unsound or defective intellect.

THE MEDICAL CIRCULAR.

WEDNESDAY, JULY 20, 1864.

THE CONSTITUTION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At the anniversary dinner which lately took place on the occasion of the election of Councillors to the Royal College of Surgeons of England, Mr. Arnott, the chairman, referred in terms of justifiable eulogy to the magnificent results achieved by some of the corporations of this country, including those connected with the Medical Profession. He referred in particular to the scientific growth of the College of Surgeons, which, without any assistance from the State, had raised up and maintained a splendid museum and a most extensive and well-selected library, the former having originated in the purchase of John Hunter's collection, which was rejected by the Government of the day. But when Mr. Arnott included the London University in the same category with the College of Surgeons, and pointed to the scientific eminence of that body as another instance of independent vitality, he committed an egregious mistake, inasmuch as the London University owes its eminence to those very circumstances of Government support in which the College of Surgeons is entirely deficient.

The London University, in fact, *is* supported by the Government; and if it had not been so sustained, it would have been strangled in its birth, notwithstanding the high character of its office-bearers and the enlightened schemes of education and examination which it has devised and promulgated. In a pecuniary sense, it has *not* been successful; and, at the present moment, it neither pays its ordinary expenses nor has it even a building of its own wherein to hold its meetings, not to mention the entire absence of any museum or library, or any other visible evidence of its existence. It is merely an examining body, partly self-supporting and partly maintained by the nation; and it has been enabled to take a high stand as an educational corporation chiefly by the possession of that Government support which is withheld from most other corporations. We do not mention these circumstances in disparagement of the London University, but with a totally opposite sentiment, as we shall presently show.

In contradistinction to the London University, the College of Surgeons of England has been, in a pecuniary sense, highly successful; and the evidence of this success is manifest in the stately building which adorns one side of Lincoln's-inn fields, the extensive and really unrivalled museum which that building contains, the well-stocked library under the same roof, and the munificent salaries enjoyed by many of the officers of the establishment. All this is done, it is true, without any Government or other public assistance, and the whole of the cost is defrayed by sums of money extracted from the pockets of a very hard-worked and ill-paid Profession, in exchange for diplomas. But can it be said with truth that the College of Surgeons has done much in promoting the diffusion of general science, or even of surgical science, among the members of the Medical Profession, or that it has taken the lead in any of those great movements by which the present era of Medicine has been distinguished? Why, so far from this having been the case, the College has adopted no improvements at all, until they have been forced upon it from without; and its whole aim and object appear to have been to make money to turn into the College coffers. An examination in Surgery, which, even now, is of a most superficial character and wholly unworthy of the present state of science; the sale of a great number of fellowships at ten guineas a piece, the fellowships by examination being comparatively very few; the institution of a separate midwifery examination, with no other object on earth that we could ever discover except to screw out from some foolish persons a few guineas more; and the grant of licences in Dentistry, with apparently exactly the same object;—all these are the recent doings of the College of Surgeons, which does not even pretend to be actuated by any other motive than the accumulation of money for the maintenance of the institution. It is quite true that the institution is, in its material aspects, an honour to the country; but in its relations to the Profession, it deserves anything but unqualified commendation.

Until within a very recent period, the examinations for the membership of the College were perfectly childish—a few questions being asked and answered, in the space of about a quarter of an hour or twenty minutes, formed the only ordeal to which the candidate was subjected, except the extraction of twenty guineas from his pocket. For this sum he received a diploma, signed, indeed, eminent by many members of the Surgical Profession, but really conveying no assurance that he had been either thoroughly educated or carefully examined. In later years, it is true that the examinations have somewhat extended and improved; but they are still very far below the exigencies of the occasion, and utterly insufficient as tests of a competent knowledge on the part of the candidate, as has lately been abundantly proved by Dr. Parkes, in his speech on the Army Medical Examinations, made at the last meeting of the General Medical Council.

Now, the practical deduction we would make from these remarks is, that the price of the diploma ought to be less, and the examination ought to be more efficient. The answer we should receive would of course be, that if such a plan were adopted the finances of the institution would suffer, and, in fact, that the diploma is offered on easy terms, as far as intellectual ability is concerned, in order to attract as many candidates as possible within the portals of the College. But it is perfectly monstrous that an institution, however splendid may be its exterior, or however valuable its contents, and we may add, however eminent its governing body, should be supported solely by the granting of diplomas; and we may add further, it is an abuse of the most flagrant kind that the Examiners and the Governing Body should be virtually the same persons, and that they should draw enormous salaries depending entirely on the number of candidates who are passed. It is quite idle to assert, what no doubt is perfectly true, that the examiners are

men of the highest personal honour, and moreover, that they are paid so much for each candidate, whether successful or not; the fact still stares us in the face, that the institution itself and the salaries of the examiners depend almost wholly upon the number of diplomas granted, and therefore the same stringency which is shown at the London University cannot be observed at the College of Surgeons.

Surely it would be better for the State to take upon itself the care of the really magnificent museum and library, which are national objects of admiration, and thus to relieve the College of what must be considered a traffic in diplomas. If such had been, or were now, the case, and if the examiners had been younger men, and liable, like other examiners, to periodical removal from office, the examinations might be real tests of professional attainments, and we should never have heard anything of special examinations and diplomas in Midwifery or in Dental Surgery, which are mere expedients to fill the College exchequer, and were never intended either to promote the progress of science, or to add to the dignity or the honour of the Medical Profession.

THE ROYAL COLLEGE OF PHYSICIANS AND THE APOTHECARIES.

Our contemporary, the 'Lancet,' has been amusing itself and its readers by a piece of jocularity for which we really should not have thought of giving it credit. It appears that a few gentlemen holding the licence of the London Apothecaries' Society have requested to be admitted as Licentiates of the Royal College of Physicians on some easy terms which are not definitely announced, but the main features of which, as far as we can learn, are the exemption from examination, and the non-payment of any fees, or at least the payment of nominal ones—say half a sovereign, for instance. For this privilege, to be granted in such a liberal manner, the petitioners magnanimously offer to present, in exchange, the license they already hold from the Apothecaries' Society.

That the College will grant so absurd a request is highly improbable, especially as it has nothing to gain by the concession. If, indeed, some ten thousand members of the Medical Profession were to offer ten guineas each as the price of the College Licence, the Council might hesitate in declining the golden prize; but still, notwithstanding the act of injustice and wrong which they committed to their own members in 1860, by selling for ten guineas the diplomas which were formerly obtained only by the payment of nearly six times that sum and the ordeal of a strict examination, we do not believe that the College would be guilty of so flagrant a breach of common honesty as that which it is now asked to commit. It has instituted an examination for such persons as choose to submit themselves to the trial, and the examiners are gentlemen of reputation and character; the terms of the examination are, moreover, lenient to those who are already in practice or in possession of other medical licenses and diplomas, and the fee to be paid is by no means immoderate. If, therefore, any gentlemen aspire to the College Licence, they can obtain it in the same way that they may obtain any other professional title or distinction—namely, by conforming to the rules laid down by the various Medical Examining Boards.

It is needless to waste words upon such a preposterous proposal, which cannot have been ever seriously made, and to which the College cannot accede without a total sacrifice of all self-respect. If the College licence is worth having (and we by no means assert that it is not), it is worth working and paying for, and its sale for a sum of money, or its gratuitous distribution to all comers, would be simply disgraceful to the College, and would be a re-enactment of the contemptible farce so often played by needy or unscrupulous vendors of degrees, or hunters after popularity. Already the finger of scorn points at certain German degrees, bought and paid for like tobacco-pipes, or any other saleable commodity, and the College of Physicians would sink into the lowest abyss of degradation if it followed so flagitious an example.

If the proposal was intended as a "feeler," it has evidently failed in its aim; for the very same Journal which promulgated it and promoted its object, now fills its pages with correspondence containing contemptuous denunciations, not only of the folly, but of the flagrant dishonesty of the scheme, especially towards those who have already obtained the licence by the usual means.

SUMMARY OF THE WEEK.

THE GRIEVANCES OF THE ARMY MEDICAL OFFICERS.

The Metropolitan Counties' Branch of the British Medical Association has, with praiseworthy perseverance, followed up their interview with the Secretary at War by subsequent deputations to the Commander-in-Chief and to the Director-General of the Army Medical Department. We regret that we have not room for the insertion of the particulars of these interviews, of the representations made by the different speakers, or of the answers made by the persons in authority. But we the less regret this omission, as the memorials and the remonstrances made by the deputations appear to have produced very little impression upon the parties addressed, more especially the Commander-in-Chief, his Royal Highness giving to every remark the stereotyped answer, that the redress sought for was either inconsistent with the maintenance of discipline in the army or would interfere with financial arrangements. He held out no hope whatever that the authorities at the Horse Guards would concede any of the points so strongly urged by the advocates of reform in the Army Medical Service. The Director-General of the Army Medical Department expressed his great sympathy for the members of the service of which he is the present chief, and showed that the withdrawal of the Warrant of 1858 had taken place before he was appointed to office. His observations to the deputation on the subject of the present dearth of candidates for the Army Medical Service, and on the means at present being taken for supplying it, were very unsatisfactory, and seemed to show that the Army autho-

rities did not wish to encourage first-class men to enter the service.

MR. WALTER COULSON AND THE HOSPITAL FOR STONE.

Mr. Walter Coulson has involved himself in some trouble by an unfortunate speech made by him at a dinner lately held in order to promote subscriptions for an Hospital for Stone, to which he is attached. He was reported in one of the daily newspapers to have represented the mortality of cases of stone in the general hospitals to be enormously high; while, in the process which the Stone Hospital proposed to adopt, not one case in fifty would be lost. He moreover was said to account for this great mortality in the general hospitals by the circumstance that those establishments could not afford sufficient time for the cases admitted, and that, therefore, a special institution was necessary for the treatment of stone. This extraordinary speech attracted so much attention that the general hospitals were compelled, in a measure, to defend themselves from the imputations thus thrown out against them; and Mr. Walter Coulson then complained that his speech had been misreported. But then came evidence from parties present at the meeting as to the substantial truth of the report; while others, friends of Mr. Coulson, represented that that gentleman had only instituted a general comparison between the mortality from lithotomy as compared with that from lithotrity. The truth probably is, that Mr. Walter Coulson, in his injudicious zeal for the new hospital, which the 'Lancet' calls "a notorious house of professional ill-fame," made some remarks which he would have done better to withhold; but as he is a young man, and the observations were made after dinner, the animadversions on his speech will teach him to be more cautious in future.

GENERAL CORRESPONDENCE.

ALLEGED BREACH OF PROFESSIONAL ETIQUETTE.

To the Editor of the Medical Circular.

SIR,—Will you kindly insert the accompanying correspondence. You will see that Mr. Adams still stoutly denies the truth of the statements contained in my letter to the College of Surgeons, but which I, on the contrary, persistently assert.

The action which my solicitors have commenced against that gentleman will afford us the opportunity for which I am, and I should think Mr. Adams must be, most anxious, to have the question submitted to a jury; and I feel sure that Mr. Adams will not permit any technicality to be interposed so as to prevent the real question—"Aye or no", are the statements "true" or "false"?—from being submitted for its decision. I am, &c.,

J. JONES.

London, 12 South square, Gray's inn, W.C., July 4th, 1864.

SIR,—My attention has been directed to a letter purporting to be signed by you, which appears in the 'Medical Times and Gazette' of Saturday last;—its terms are coarse, intemperate, and offensive.

I have to ask whether you are in truth the author; and if so I must insist upon its withdrawal, accompanied by an apology to be first submitted to me, and then published in all the medical papers.

You should, at the same time, express your regret for your conduct on 21st May last, and which was brought by me to the notice of the President and Council of the College of Surgeons.

If this is done, the matter shall end, so far as I am concerned; but if not, you had better direct your legal adviser to place himself in communication with my solicitors, Messrs. Langley and Gibbon, 32 Great James street, Bedford row, whom I shall instruct in due course.

I am, &c., J. JONES.

John Adams, Esq., St. Helen's place, Bishopsgate.

4 St. Helen's place, July 6, 1864.

SIR,—I beg to acknowledge the receipt of your letter of the 4th inst., in which you ask me to retract and apologise for expressions employed in my letter to the 'Medical Times and Gazette,' which you designate as coarse and intemperate. You must remember that your insinuation of unprofessional conduct, in your statement in the same paper, provoked those expressions.

Nevertheless, although I explicitly deny the truth of your statements, as I believe you have been influenced by erroneous information, I shall not hesitate to retract those hasty expressions contained in my letter; and, I need not say, this retractation necessarily implies an apology for the same. I have explained my conduct in Metzner's case, in a communication I have sent to the 'Medical Times and Gazette' in answer to one from you.

I am, &c., JOHN ADAMS.

Jno. Jones, Esq.

GRIFFIN TESTIMONIAL FUND.

To the Editor of the Medical Circular.

SIR,—The following subscriptions have been further received on behalf of the above fund:—

	£	s.	d.
Henry Ewen, Esq., Wisbeach	0	10	0
A. B. Ewen, Esq., Wisbeach	0	10	0
J. Smart, Esq., Bethnal green	1	1	0
Robert Cuff, Esq., Holborn	0	10	6
J. Blundell, Esq., St. Helen's, Lancashire	1	0	0
J. Bryant, Esq., Clerkenwell	0	5	0
Dr. W. Garstang, Blackburn	0	10	0
Robert Lamb, Esq., Islington	0	5	0
R. W. Watkins, Esq., Towcester	0	10	6
Dr. J. T. Barrett, Ashton-under-Lyne	0	10	0
G. E. Piper, Esq., Darlington	1	1	0
A. D. Harston, Esq., Islington	1	1	0
Dr. J. Rogers, Strand	1	1	0
Dr. Whiteman, Putney	0	10	6
G. E. Nicholas, Esq., Wandsworth	0	10	6
Amount previously announced	7	2	0

Yours obediently,

145 Bishopsgate st. Without. ROBERT FOWLER, M.D.
July 13, 1864. Treasurer and Hon. Sec.

THE MEDICAL PROVIDENT ASSOCIATION.

To the Editor of the Medical Circular.

SIR,—I am most happy to see the subject of a "Medical Provident Association" again mooted in "Alpha's" letter in your last CIRCULAR. I hope you will lend your powerful aid and put your shoulder to the wheel this time to obtain for us now a strong and good Medical Club, on the principle of the Railway Accident Societies, which give from three to six guineas per week in case of any injury, but not in *sickness*. Why not convert this or the "British Medical and Surgical Association" into a fund of this kind, where every subscribing member will have a just *claim* of this description (according to the amount of his subscription), and a sum at his death to bury him, or for the support of his surviving widow or family, &c.? This would be a far greater boon than their 'Association Journal' or "Benevolent Fund" will ever be; and I have no doubt but, with proper management, it can be carried out with very little extra expense.

Hoping you will not let this important subject-matter drop this time, I am, &c.,

BETA, M.R.C.S.E., L.S.A., and L.M. Dub., and an Ex-Member of the Association.

Oswestry, Salop, July 16, 1864.

MEDICAL SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 17.

Mr. PRESCOTT HEWITT, President, in the Chair.

(Continued from page 30.)

Mr. HUTCHINSON also brought forward a specimen of MORGAGNIAN CATARACT, WITH DISPLACEMENT OF THE NUCLEUS.

An elderly woman applied at the Moorfields Hospital with double cataract. In the right eye the lens presented the usual grey appearance, but in the left a horizontal line across the pupil divided the opaque lens into an upper white half and lower rich brown one. The line of demarcation was most abrupt, and produced an appearance much resembling that of a parti-coloured agate. It was thought at first sight that the lens must be fluid, and that the coloured particles had gravitated to the lower part; but it was found that, in changing the position of the patient's head, no change in the relation of the coloured and uncoloured parts could be effected. The fact that the line of separation was almost level seemed to negative the idea that the coloured part was the nucleus, which having become loosened had sunk down. Mr. Hutchinson performed extraction in both eyes. The lens of the right was grey in colour, and a little brown towards its middle; its surface was sticky and soft, but not fluid. The lens of the left eye presented the condition of a fluid exterior, with a very hard red-brown nucleus. The latter, quite loose, had sunk down to the lowest part of the capsule. It was not round, but a very long oval, so that its long side, which had lain uppermost, had appeared to cross the pupil, not as a curved, but as an almost straight line. As to the question whether Morgagnian cataracts might be held to indicate unsound eyes, Mr. Hutchinson remarked that there was no reason in this case to suppose that the globe was diseased. It had progressed perfectly well since the operation. The cataract had existed about four years before the patient applied.

Dr. OGLE related the following

CASE OF CARIES OF THE FIRST AND SECOND CERVICAL VERTEBRÆ—FISTULOUS OPENING COMMUNICATING WITH THE DISEASED BONE—RUPTURE OF TRANSVERSE LIGAMENT—SUDDEN DEATH BY PRESSURE OF ODONTOID PROCESS UPON THE SPINAL CORD.

The patient, aged sixteen, was the subject of intense pain, shooting from the neck to the top of the head, and of almost complete inability to move the head, along with great rigidity of the sterno-cleido mastoid muscles on both sides. Through the fistulous opening at the back of the neck above alluded to, dead bone could be felt. Loss of power over the left arm and leg came on; afterwards, paralysis of the sphincters and loss of power in all the limbs. He died whilst attempting to raise his head in bed. On post-mortem examination the spinal cord corresponding to the axis was quite softened, the result, no doubt, of pressure of the odontoid process. For the opportunity of exhibiting the specimen, Dr. Ogle was indebted to Mr. Barber, surgeon to the Sheffield Infirmary. Dr. Ogle related in connection with this case three others of disease of the upper cervical vertebræ.

The first was the case of the late Dean of Westminster, the Very Rev. Dr. Buckland, in whom, after death, he had found *extensive caries of several of the upper cervical vertebræ, including the odontoid process, with great destruction of the ligamentous structures.* The "transverse ligament" was much diseased, and easily ruptured, but it had not actually given way before death. The occipital bone around the foramen-magnum was also carious. The brain and cerebellum were healthy, excepting a slight amount of fatty degeneration of the capillaries in places.*

* The specimens of diseased vertebræ and occipital bone have been deposited by Mr. F. Buckland in the museum of the Royal College of Surgeons.

The second case alluded to was one of *caries of the first and second cervical vertebræ and abscess communicating therewith, rupture of the "transverse ligament," and sudden death from dislocation of the odontoïd process.* The patient was an inmate of St. George's Hospital, in whom, before death, the loss of power in moving the head became so affected that it had to be kept fixed by means of a pillow of sand.

The third case was one of *caries of the first and second cervical vertebræ and of the base of the cranium, with enlargement of the odontoïd process, and softening of the corresponding part of the medulla oblongata.* Intense pain came on, following what was thought to be a "stiff neck," and eventually he was obliged to support his head with his hands. Twitchings of the arms, dyspnœa, and dysphagia came on. Before death speech failed him, and dyspnœa became extreme.

Dr. OGLE also described the following case:—

HEMIPLEGIA ON THE RIGHT SIDE—SOFTENING OF THE BRAIN ON BOTH SIDES—PLUGGING-UP OF BOTH MIDDLE CEREBRAL ARTERIES BY FIBRINOUS COAGULUM—FIBRINOUS MASSES ADHERENT TO THE MITRAL VALVE-FLAPS AND TO THE LINING OF AURICLE, WHICH WAS ULCERATED AND THE SEAT OF CALCAREOUS DEPOSIT.

The case was that of an anæmic girl, aged twenty-one, who, a few days before admission into St. George's Hospital, had had some sort of a "fit." Her face was anxious; her articulation defective; her words being "clipped," and running one into the other. There was almost complete motor paralysis of the right arm and leg, the tactile sensibility of the skin being much exalted. Later on she miscalled objects and used "wrong" words. An albuminous state of the urine came on, also great quickening of the respiration and circulation. She sank and died three weeks after admission. After death softening of the *left* corpus striatum and of the anterior part of the middle cerebral lobe on the *right* side was found; also plugging-up of the commencement of both middle cerebral arteries by fibrinous coagulum, and masses of fibrin adherent to the heart's valves and inner surface of left auricle, as above stated. Blocks of fibrinous material also existed in one kidney.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

ABSTRACT OF THE REPORT OF THE COMMITTEE ON CHLOROFORM.

In laying their report before the Council of the Medical and Chirurgical Society, the Committee on Chloroform desire to state that they have made comparatively little reference to the medical portion of the subject. This is not due to their thinking the medical uses of chloroform of little importance, but to the fact that but few replies to their inquiries upon this point have been received.

In view of the great extent of the subject submitted to their consideration, the committee directed their attention to such points as appeared to them of chief practical importance. Thus their observations respecting the action of chloroform on the nervous system, and their remarks on some other points, are less full than would have been desirable had the committee regarded such details as of equal importance with those specially elected for investigation—such as its influence on the action of the heart and on respiration.

The committee have chiefly confined their physiological report to observations which they have themselves made. Without overlooking or neglecting the labours of former investigators, they have endeavoured rather to furnish an accurate account of experiments which they have observed carefully and together, and to compare the results thus obtained and agreed upon with the phenomena of cases in which death or peril of life has arisen from the inhalation of chloroform in the human subject.

Physiological Conclusions.—The sequence of the phenomena produced by chloroform inhalation in animals is similar to that observed in man, and if the same percentage of the agent be administered the results produced are

nearly uniform. The first effect of chloroform vapour is to increase the force of the heart's action ; but this effect is slight and transient, for when complete anæsthesia is produced, the heart in all cases acts with less than its natural force. The strongest doses of chloroform vapour, when admitted freely into the lungs, destroy animal life by arresting the action of the heart ; whilst by moderate doses the heart's action is much weakened for some time before death ensues, respiration generally, but not invariably, ceasing before the action of the heart, death being due both to the failure of the heart's action and to that of the respiratory function. The danger attending the use of chloroform increases with the degree of stupor it induces ; the apparent irregularities in the action of the anæsthetic mainly depending on the varying strength of the vapour employed, on the quality of the chloroform, and on the constitution of the patient. In order that it may be administered with comparative safety it is necessary that the proportion of vapour should not exceed 3½ per cent., that its effects should be carefully watched, and the inhalation suspended when the required anæsthesia is induced.

In many respects the action of ether is similar to that of dilute chloroform. At first its vapour increases the force of the heart's action—an effect which is both greater and of longer duration than that observed with chloroform. The stimulation is followed by a depression of the force of the heart's action, but at the same degree of insensibility ether does not depress the action of the heart to the same extent as chloroform. Eventually ether kills partly by enfeebling the action of the heart, but chiefly by arresting the movements of respiration. Thus the energy with which chloroform acts, and the extent to which it depresses the force of the heart's action, render it necessary to exercise great caution in its administration, and suggest the expediency of searching for other less objectionable anæsthetics. Ether is slow and uncertain in its action, though it is capable of producing the requisite insensibility, and is less dangerous in its operation than chloroform. On the whole, however, the committee concur in the general opinion which in this country has led to the disuse of ether as an inconvenient anæsthetic.

A mixture of ether and chloroform is as effective as pure chloroform, and a safer agent when deep and prolonged anæsthesia is to be induced ; though slow in its action, it is sufficiently rapid in its operation to be convenient for general use. A mixture composed of three parts of ether, two parts of chloroform, and one part of alcohol (by measure), is to be preferred on account of the uniform blending of the ether and chloroform when combined with alcohol, and the equable escape of the constituents in vapour ; and the committee suggest that it should be more extensively tried than it has hitherto been in this country.

Effects of Chloroform on the Fauces.—The sudden administration by the mouth of concentrated chloroform vapour induces a spasm of the fauces which lasts for some seconds; afterwards, when the animal has inspired, the phenomena of asphyxia are for a time, associated, with those of chloroform poisoning, and death is finally induced as by dilute chloroform. If, however, partial insensibility is first induced by weaker chloroform, no spasm of the fauces ensues upon the sudden administration of the concentrated form of the agent.

Post-mortem Appearances.—Judging from the observations on animals,—the appearances in the human subject having been noticed in but few cases, and being insufficient for yielding satisfactory conclusions,—it appears that though there may, in certain cases, be an impediment to the free circulation of the blood through the lungs, yet the appearances are very different after death has been caused by chloroform from those observed when life has been destroyed by asphyxia. In death from chloroform, all the cavities of the heart are distended, and the cases are only exceptional in which the left side is empty. The rule, however, is alike in both : that the cavities of the right side contain more blood than those of the left.

Resuscitation.—The most certain means of restoring life after poisoning with anæsthetics is by artificial respiration. By this means resuscitation may generally be accomplished after natural respiration has ceased, provided the heart continues to act, and it may *sometimes* be effected even after the cessation of the heart's action ; but this result is exceptional. Galvanism resuscitates within the same limits as artificial respiration ; it is, however, far less to be relied on than artificial respiration in equal cases. With either remedy it is found that animals quickly rendered insensible by a strong dose are more easily recovered than those which have been gradually narcotised even by a small percentage of the anæsthetic.

Rules relating to the Administration of Chloroform.

The anæsthetic should on no account be given carelessly, or by the inexperienced ; and when complete insensibility is desired, the attention of its administrator should be exclusively confined to the duty he has undertaken.

Under no circumstances is it desirable for a person to give chloroform to himself.

It is not advisable to give an anæsthetic after a long fast, or soon after a meal ; the best time for its administration being three or four hours after food has been taken.

If the patient is much depressed, there is no objection to his taking a small quantity of brandy, wine, or ammonia, before commencing the inhalation.

Provision for the free admission of air during the patient's narcotism is absolutely necessary.

The recumbent position of the patient is preferable ; the prone position is inconvenient to the administrator, but entails no extra danger. In the erect or sitting posture there is danger from syncope. Sudden elevation or turning of the body should be avoided.

An apparatus is not essential to safety if due care be taken in giving the chloroform. Free admixture of air with the anæsthetic is of the first importance, and guaranteeing this, any apparatus may be employed. If lint, or a handkerchief, or a napkin is used, it should be folded as an open cone, or held an inch or an inch and a half from the face.

The anæsthetic should invariably be given slowly. Sudden increase of the strength of the anæsthetic is most dangerous. Three and a half per cent. is the average amount, and four and a half per cent. with ninety-five and a-half of atmospheric air is the maximum of the anæsthetic which can be required. Given cautiously at first, the quantity, within this limit, should be slowly increased according to the necessities of the case, the administrator being guided more by its effect on the patient than by the amount exhibited.

The administrator should watch the respiration of his patient, and should keep one hand free for careful observation of the pulse.

The patient who appears likely to vomit whilst beginning to inhale the anæsthetic should be at once brought fully under its influence, and the tendency to sickness will then cease.

The occurrence during the administration of an anæsthetic of sudden pallor or of sudden lividity of the patient's countenance, or sudden failure or flickering of the pulse, or feeble or shallow respirations, indicates danger, and necessitates immediate withdrawal of the anæsthetic until such symptoms have disappeared. On the occurrence of these symptoms, and especially if they should become so urgent as to threaten death from failure of respiration, of heart-action, or of both together, the following rules of treatment are to be observed :—Allow free access of fresh air ; pull forward the tongue, and clear the mouth and fauces ; keep or place the patient recumbent ; dash cold water on the face and chest, and aid the respiratory movements by rhythmical compression of the thorax. In the more threatening cases artificial respiration must be commenced instantly ; and this rule applies equally in all cases, whether the respiration has failed alone, or the pulse and respiration together. Galvanism may be used in addition to artificial respiration, but the artificial respiration is on no account to be delayed or suspended in order that galvanism may be tried.

Few if any persons are unsusceptible of the influence of chloroform, from two to ten minutes being required to in-

duce anæsthesia. The time, however, varies with age, temperament, and habits.

The mixture of chloroform, ether, and alcohol should be given in the same way as chloroform alone; care being taken, when lint or a handkerchief is used, to prevent the too free escape of the vapour.

Use of Chloroform in Surgical Operations.

With heart-disease the anæsthetic may be given in any case which requires an operation, although, when there is evidence of a fatty, weak, or dilated heart, great caution is demanded. Valvular disease is of less importance.

In phthisis, when an operation is unavoidable, the anæsthetic may be given with impunity.

For all operations upon the jaws and teeth, the lips, cheeks, and tongue, the anæsthetic may be inhaled with ordinary safety. By care and good management the patient may be kept under its influence to the completion of the operation. In these cases, blood as it escapes, if not voided by the mouth, passes into the pharynx. If any small quantity finds its way through the larynx, it is readily expelled by coughing. In operations upon the soft palate, fauces, pharynx, and posterior nares, if sudden or severe hæmorrhage is likely to occur, it is not advisable to induce deep insensibility.

In cases requiring laryngotomy and tracheotomy the anæsthetic may be employed with safety and advantage.

For operations upon the eye, involving the contents of the globe, the use of anæsthetics is open to objection on account of the damage which the eye may sustain from muscular straining or vomiting. If employed, profound insensibility should be induced.

In operations for hernia, and in the application of the taxis, the anæsthetic acts most beneficially. For most operations about the anus, profound anæsthesia is positively demanded.

In the condition of shock, or of great depression, as after hæmorrhage, careful administration of the anæsthetic diminishes the risk of an operation.

In all cases, other than those specially referred to, it is sufficient to state, so far as a mere surgical operation is concerned, that an anæsthetic may invariably be administered.

The continuous vomiting occasionally induced by and following upon the inhalation of anæsthetics may be injurious by consequent exhaustion, as well as by mechanically disturbing the repair of a wound. With this reservation, they do not appear to interfere with the recovery of patients from surgical operations.

Statistics.—The results of 2,586 capital operations performed before, and of 1,860 performed since, the introduction of anæsthetics, collected from all authentic available sources, prove that anæsthetics have in no degree increased the rate of mortality.

Use of Chloroform in Obstetric Practice.

(*a*) *In Natural Labour.*—The careful administration of chloroform during labour is not attended with special danger, there being, either in this country or abroad, so far as is known to this committee, no well-authenticated instance of sudden death where it has been given by a medical practitioner; but the occasional occurrence of unfavourable symptoms demands the exercise of caution during its employment. Administered in a moderate degree, it does not, as a rule, weaken the expulsive powers, and is decidedly beneficial in promoting dilatation of the maternal passages. It does not predispose to puerperal convulsions or other like complications. The balance of opinion is nearly equal as to whether it predisposes to imperfect contraction of the uterus after delivery. As a rule, it in no way retards the convalescence of the mother; nor has it any tendency to interfere injuriously with the function of lactation; nor has it any injurious influence on the child.

(*b*) *In Abnormal Labour.*—The anæsthetic may be employed with advantage in various obstetrical operations—as forceps, turning, craniotomy, and extraction of retained placenta, —unless the patient is much enfeebled by hæmorrhage; when, if given, it ought to be accompanied by the use of stimulants. It may also be employed advantageously to check the paroxysms in puerperal convulsions.

(*c*) *As to the Preference of Ether. Rules relating to the Administration of Chloroform.*—There are no reasons for giving preference to ether over chloroform, the latter being much more desirable in obstetrical practice generally, the only exceptions being those in which chloroform notably disagrees.

In addition to those given for its administration in ordinary cases, it is generally desirable to observe the following rules during its administration in labour, subject to modifications at the discretion of the practitioner:—In natural labour, begin to give it generally at, or after, the termination of the first stage; but it may be given earlier if the first stage is unduly painful, or if the os uteri resists dilatation. Give it only during the pains, and withdraw it in the intervals. When the fœtal head bears on the perinæum give it more freely, to promote relaxation and relieve the increased pain. Withdraw the chloroform immediately after the child is expelled. If the patient is depressed, or the pains are sluggish during its administration, an occasional stimulant may be administered. In cases where it seems to interfere with the progress of labour it may be necessary to suspend its use for a time, and re-apply it after an interval, or even to withdraw it altogether. In turning and instrumental deliveries deep anæsthesia must be induced, as in surgical operations; and the administration should then be entrusted to a competent person, whose sole duty should be to attend to it. In midwifery a special inhaler for its administration is not generally necessary or desirable, a handkerchief or towel, folded so as to prevent blistering of the face, and to allow free admixture of atmospheric air, being sufficient for the purpose.

(*d*) *Use of Chloroform in Diseases of Women and Children.*—In the treatment of diseases of women, chloroform may be employed to facilitate and lessen the pain of certain examinations. In cases of spurious pregnancy and phantom tumours, by relaxing the abdominal parietes, it may assist in demonstrating their true characters; and, acting in the same way, it may help the practitioner to define more accurately the character and relations of other abdominal and pelvic tumours, or to detect feigned disease.

As a therapeutic agent, its inhalation, and external application in the form of a liniment, may be usefully employed to allay pain in some cases of severe dysmenorrhœa, neuralgia, and the like.

There is accumulated testimony in favour of chloroform inhalation proving serviceable in various spasmodic diseases of women and children: as whooping-cough complicated with convulsions, spasmodic croup, epileptic seizures, and some other forms of convulsion in children; hysterical convulsions, epilepsy, and various muscular contractions in women.

The PRESIDENT expressed in warm terms the obligations the Society were under to the Committee for their able and laborious report.

Mr. CURLING regretted that so much time had elapsed since the Committee had been formed. But, as would appear when the paper and the appendix were published, much more work had been done than would be thought from the part of the abstract which had been read. There had been a division of labour into three chief departments: physiological, surgical, and obstetrical. But the most work had been done by the first section—the physiological. This section had had seventy meetings, and had performed very many careful experiments. When all this was taken into consideration the Fellows would not be surprised that the report had been delayed. The Committee wished to acknowledge the support afforded by many Fellows of the Society and by the Profession generally. Mr. Curling said that he must allude more pointedly to the labours of the reporters, Mr. Sibley and Mr. Callender. These gentlemen had attended all the meetings of the Committee, and it was, after hearing the report, scarcely necessary to express any opinion as to the great zeal, devotion, and intelligence they had displayed.

Dr. KIDD said a great debt of gratitude was due to Mr. Curling and the Physiological Committee for their incessant labours; yet he could not help thinking the great chloroform question at present was, as to its safety or use, a

question of practical or empirical observation in hospitals rather than a question of physiology. Nobody denied that very large doses killed animals. We had similar experiments in vast number in books, but the deaths in practice in the human subject are from idiosyncrasy (from which the lower animals are free), from errors of administration, emotion, fright, in the convulsive or preliminary stage before deep anæsthesia at all, deaths from spasm of the glottis, apnœa, almost always in trivial operations, like tooth-drawing, rather than in the half-hour's deep narcotism of large operations. Physiological experiments, such as dropping chloroform on the heart of a frog, or throwing it into the peritoneum, are fallacious; the experiment kills, but not the chloroform. Then, as to "mixtures" of anæsthetics, they have been used extensively in Austria and France, even by order of Government. The ether was found to be first inhaled, then the chloroform, and the spirit of wine remains behind and has to be squeezed out: they tend towards mystery and are cumbersome. The best part of the report is as to the value of electro-magnetism in resuscitation; but it is an error that the little magnet-box is not accessible in hospitals. It is equivalent to saying saving life is not important. The midwifery portion of the report does not offer much that is new, and so of the general surgery part; but both are good. But as to the use of chloroform in medicine it is deficient, as this agent is most valuable in asthma, pain of gall-stones, tetanus, convulsions of women, whooping-cough, and a dozen other affections.

There is at surgical operations now less arterial but more venous blood than formerly: even vomiting will fill a wound with blood (secondary). Chloroform is safe in what is termed shock or collapse. This is the "law of tolerance" so well described by Miller; but surgeons do not read of empirical rules so much as physiological experiments. The speaker fully agreed as to the great value of artificial respiration in accidents, but that was best set up by the electro-magnetism box, as now extensively tried. It is true also that resuscitation is more difficult in ether accident cases than from chloroform.

Dr. HYDE SALTER said a point had been overlooked, but on which it was not possible for the Committee to have investigated in so short a time as they had taken for their report. It was as to the effect on the human constitution of chloroform administered for months or for years. He offered this as a suggestion for further investigation. Dr. Salter then related the case of a gentleman who for three years had taken chloroform, nearly every night. The effects were somewhat like those of alcohol: general loss of nervous power, insomnia, and vomiting in the morning. The chloroform was taken for asthma, and sometimes as much as three ounces was inhaled in one night. The effect was most distressing. The patient lost appetite, became morose, and was unable to sleep. He for one month was able to avoid it, and the improvement was most marked. He got to sleep earlier and earlier every night. This, however, the patient ascribed to Indian hemp, which he took at the time; but on taking the chloroform again, he again had insomnia, and Indian hemp failed to help him. The vomiting in the morning was like that of drunkards. Mr. Salter considered that in other respects the effects would be found to resemble those of alcohol.

Mr. SAVORY asked under what circumstances and to what extent, in collapse from injuries or from hæmorrhage, chloroform might be administered. It was true that it would tend to diminish shock; but it would, on the other hand, be likely to render the pulse almost imperceptible. It was a point of great interest that chloroform tended to reduce the temperature, even, as some experiments showed, seven or eight degrees. In collapse, too, the temperature was diminished; and hence, if chloroform were given, there would be two conditions tending to the same result.

Dr. C. J. B. WILLIAMS said there could be but one opinion as to the great debt the Society owed to the Committee—a debt which the Society was scarcely able fully to appreciate until the publication of the report. One important point was, however, settled; that chloroform depressed the action of the heart. This was an important result, as it had been much disputed. It accorded with the results of experiments he himself had performed; and the histories of cases of death from chloroform all converged to the same point. This in itself helped to suggest methods of counteracting the effect of too large a dose. One obvious method was to add ether and alcohol to the chloroform. But there was no reason why alcohol, ammonia, or any other stimulant, should not be given by the mouth. Oxygen had been suggested, and had, it was said, been used in America with success; and it was not improbable that chloroform and oxygen might form a useful and safe combination. One class of anæsthetics had not been alluded to—namely, nitrous oxide. From his own observations some years ago, it appeared to be not so depressing, and it was safe. But there were difficulties in procuring it, and in applying it. Dr. Williams then alluded to the effect of chloroform on the blood, and asked what researches the Committee had made in this part of the subject.

Dr. KIDD observed that two deaths were published this year from nitrous oxide used as an anæsthetic, so that it is not free from accident, as Dr. Williams might have supposed. As to the use of a little brandy or ammonia before administration, the plan was a good one, and always adopted by himself. Then as to the blood, it was perfectly known, from hundreds of experiments, that chloroform does not disturb its character at all. But it was not so with ether; here the corpuscles are destroyed, and the ether was so dissolved in the blood that it had been distilled over and over again from the blood of an animal deeply narcotized by it. Crystals were of less moment in blood long drawn. Forty-one deaths from ether had been published in America, and nineteen by Trousseau in France. It seemed paradoxical that chloroform administered in small doses should be dangerous. But it was small doses which produced convulsive vomiting: and so death in hospitals began as a sort of spasm or convulsive irritation of the fauces and glottis, while the patient was half conscious, not in deep coma; with a sort of reflex or tetanic rigidity of the respiratory muscles; the heart still beating actively, till overpowered or engorged at the right side. Hence the great value of artificial respiration. The breathing, in fact, stopped; and yet the patient did not inhale the large percentages given to animals, the chloroform at boiling point in balloons, &c. It seemed paradoxical to deny physiological experiments, but we did not prevent glaucoma or ague by physiology, but rather by empirical rules; so was it with regard to chloroform and prevention of accidents. Oxygen, too, had been tried, but found wanting: the blood was not deoxygenised, at least by chloroform. Anæsthesia was like hybernation. The blood would not take up pure oxygen. In a case at a Borough hospital where oxygen was accurately tried it proved useless. There was a fear that students trusted too much to a complex apparatus. They did not detect the danger early enough. To them "mixtures" like those of the new Pharmacopœia would be a sort of mitigation of danger—a kind of drag to the wheel of anæsthetic progress. Nor did the heart first stand still, as supposed by some; it was a popular error. While as to nitrous oxide and even ether, they were both now given up in America, where they had been extensively administered.

Dr. WYNN WILLIAMS recommended that in collapse from chloroform warm port-wine should be injected by an O'Beirne's tube. He had tried this in collapses from other causes, and had found it to act energetically. It seemed, he thought, by increasing the warmth and by giving a stimulant at the same time, to meet Mr. Savory's remarks.

Dr. BALLARD objected to that part of the report in which the use of chloroform in the convulsion of children was recommended. He was satisfied that it had no beneficial effect, and asked if its use had been recommended after a trial in cases.

Mr. CURLING said it was not recommended that chloroform should be given until reaction set in after injuries, but then it acted beneficially in the operation by diminishing shock. In reply to Dr. Ballard, he said that there commendations of the Committee were based on a series of facts, and after a large experience.

Dr. HARLEY said the action of chloroform on the cor-

puscles was but slight, but if ether were added, it dissolved the walls of the corpuscles. It had been long observed by Dr. Jackson, of New York, that chloroform produced formic acid in the system; but it was impossible to trace the changes. If blood were shaken up with ether it would sometimes crystallize. Diseased blood would also sometimes crystallize spontaneously, while blood after slow death from chloroform, when shaken up with ether, always became like a mass of crystals.

(Dr. Harley then introduced to the notice of the Society an inhaler sent to him by Dr. Skinner, of Liverpool, and also an ingenious apparatus, invented by Dr. Squire, for measuring accurately the percentage of chloroform.)

Dr. PEARSON said he was surprised to find that chloroform was more feared here than in Edinburgh, where it was invented. In Edinburgh apparatus was altogether disregarded. He felt certain that it was safer to give chloroform without an inhaler than with one.

Dr. HYDE SALTER said that chloroform might be given so as to prevent pain and yet not produce insensibility; for this he could vouch, as he had experienced it himself. If, then, it could be discovered how to do this, it would not only lessen the risk, but would diminish the fear of the use of the drug.

Dr. WRIGHT said that the inhaler had been used a year in Mr. Spencer Wells' ovariotomy operations, but it was liable to the objection that a good deal of the chloroform escaped, and thus affected the bystanders.

Mr. BIRKETT, one of the honorary secretaries, said that it had been impossible for him to read the whole of the abstract, but he had only omitted those parts which the reporters had agreed should be omitted.

BIRTH.

BARNES.—On the 7th inst., at Matfen, Newcastle-on-Tyne, the wife of W. A. Barnes, Surgeon, of a son.

DEATHS.

ACHESON.—On the 8th inst., at Dalkey, Co. Dublin, J. H. Acheson, F.R.C.S.E., Surgeon R.N., Aug. 17th, 1815, aged 77.

BIRD.—On the 10th inst., at Fern-acre Lodge, Gerrard's-cross, Bucks, J. Bird, M.D., late Physician-General to the Bombay Medical Board, aged 67.

BOWIE.—On the 3rd inst., at Bath, Wm. Bowie, M.D., aged 71.

GIBSON.—On the 7th inst., at Tarbolton, Ayrshire, John Gibson, L.F.P. & S. Glas.

HARRISON.—On the 12th ult., on board the "Macgregor Laird" off Accra, on the homeward voyage from Abbeokuta, West Africa, A. A. Harrison, M.D., aged 33.

MARRIOTT.—On the 4th inst., at Stuttgart, Dr. Marriott, late of Basle, Switzerland, aged 56.

PATTISON.—On the 6th inst., at Portland place, Bath, W. T. M. Pattison, M.D.

YOUNG.—On the 8th inst., W. P. Young, L.R.C.S.I., of James's street, Dublin, Demonstrator of Anatomy at Steevens's Hospital, Dublin.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 7th inst.:—Albert Egerton Hall, Nantwich, Cheshire; Francis Snaith, St. Thomas's Hospital; Thomas Sibley Stott, St. Bartholomew's; John Thompson, University College. As an Assistant:—James Crocker, Dorchester.

The following gentlemen also on the same day passed their first examination:—Henry Aubrey Husband, St. Bartholomew's Hospital; Francis Stewart Manisty, King's College; Anthony Herbert Martin, University College; Robert Robinson, St. Bartholomew's; Jonh Henry Simpson, St. Bartholomew's.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.—The following is a list of gentlemen who passed during the half-year ending June 30th, 1864:—James Atkinson; Charles Backhouse; Francis Bonney; Patrick Byrne; Louis A. Fleury; John Gray; James Smith Harris; Henry Head; Charles Healy; James B. Kelly; Robert Kerans; Thomas Charles Kirby; Richard Kerr M'Clement; James M'Creery; R. Alfred O'Brien; Henry Thomas O'Reilly; Richard O'Reilly; William O'Reilly; Gerald O'Toole; Thomas Chalmers Peebles; John Joseph Riordan; William Edward Riordan; Albert Benjamin Robinson; Joseph Septimus Steward; James Stewart; Robert Lafayette Swan; Richard James Sweetman; Joseph John Thompson; William Winslow Tomlinson; William Whittaker; Henry Willington.

The following gentleman was elected a Fellow of the College on the 4th ult.:—Dr. T. W. Belcher.

UNIVERSITY OF DUBLIN.—On the 29th ult. the following degrees in Medicine and Surgery were conferred:—M.B.—Edward George Clark, Austin Henry Nicholls, John R. R. Coulter, Isidore Bourke, George Fleetwood Churchill, Robert H. Macloghlin, Charles F. Green, John Alexander Wilson, George F. Duffey, John P. Boileau, John M. Finney Henry King.

M.C.—Robert H. Macloghlin, George F. Duffey, John Lyons.

M.D.—Wm. R. Wilde, Edward H. Bennett, John Ringland, John Eustace.

ROYAL COLLEGE OF SURGEONS.—The annual meeting of the Council for the election of officers took place on the 14th inst., when Mr. Joseph Hodgson, F.R.S., of Westbourne terrace, was elected President of the College in the vacancy occasioned by the retirement of Mr. F. C. Skey, F.R.S., of St. Bartholomew's Hospital; and Messrs. Thomas Wormald, of the same hospital, and Francis Kiernan, F.R.S., were elected Vice-Presidents for the ensuing year. At this meeting of the Council, Messrs. Thomas Blizard Curling, F.R.S., of the London Hospital, and Frederick Le Gros Clark, of St. Thomas's Hospital, the recently-elected Councillors, were sworn in, and took their seats. The last primary examination before the close of the session commenced on Friday, and the last pass examination for the diploma of Membership commences on Saturday, the 23rd inst.

TETANUS IN THE AMERICAN ARMY.—Tetanus has prevailed among the wounded of the Army of the Potomac to an unusual extent. Upwards of fifty cases occurred within a short period at Fredericksburg and in the hospitals at Washington. Nearly every case proved rapidly fatal. We are glad to learn that Dr. Brown-Sequard, of London, now in this country, has consented to give a lecture on this disease, at Washington, where it is now most prevalent. The great experience of this eminent physiologist in the treatment of nervous affections will thus be made available to the army surgeons in the management of this obscure and fatal complication of gun-shot wounds. This lecture will be immediately published for circulation in the army.—'American Medical Times.'

A CAUTION TO SURGEONS WANTING ASSISTANTS.—On Friday, the 8th of July, before Mr. Justice Erle and a special jury in the Court of Common Pleas, at the Guildhall, there was a case tried which is interesting to the Medical Profession at large. Thomas Nicholas Gray, who described himself as "late of the Federal army and of Dublin, sued Mr. E. J. Morris, of Adelaide terrace, Barking road, Essex, for 52*l.*, or a year's salary at 1*l.* per week, which sum Gray alleged was due to him because Mr. Morris had refused to accept of his services after having engaged him. The plaintiff swore that he had applied for a situation through Mr. Langley, of Lincoln's-inn fields, and had been put into communication with Mr. Morris, through him, on the 4th of April; that Mr. Morris had said that he would engage him, but would write to his references, whom the plaintiff admitted were not professional men. He swore that after a lapse of three weeks the defendant had sent him a letter, stating that his (Mr. Morris's) brother-in-law had consented to remain with him, and that consequently he would not require the plaintiff's services. He further alleged that his references had been written to, and that, as he was satisfied their replies were satisfactory, he claimed a year's salary for non-fulfilment of contract, and brought this action to recover it. The defendant, being sworn, declared that Gray did not come to him until the

28th of April (not the 4th, as sworn by plaintiff), and that he had written to Dr. Ledwick, of Dublin, whose name had been mentioned by Gray as a reference, and had received a reply advising him to have nothing to do with the plaintiff, but at the same time desiring him not to mention his (Dr. Ledwick's) name in the matter. On this account, he (Morris) had written the letter produced. He declined to engage Gray because this reference was unsatisfactory. Mr. Langley, medical agent, of Lincoln's-inn fields, corroborated Mr. Morris as to the date of the application, and thus destroyed the plea set up by plaintiff, that he had been kept waiting for three weeks by the defendant; he proved, also, that a month's salary only could be claimed according to custom, consequently that to demand a year's salary was an attempt at extortion; and further, that if an engagement had been concluded there would have been a fee due to him (Langley) which had never been tendered or paid, and which he had never considered to be due, and had never applied for or entered on his books. When the plaintiff applied at the office Mr. Langley had told him that his testimonials were insufficient, and that he must give Mr. Morris better references than those offered. The Judge, in summing up, pointed out that if such an action as this could be sustained, no employer of any kind—even a lady engaging a maid—would be safe. The jury, after a brief consultation, returned a verdict for defendant (Mr. Morris). We regret to learn, however, that the defence of the action has cost Mr. Morris a considerable sum of money, and that there is no probability of his recovering the costs from Thomas Nicholas Gray, late of the Federal army.

ACADEMICAL CANVASSING IN FRANCE.—In a recent oration pronounced at the Société de Chirurgie in memory of the late Professor Robert, M. Verneuil gave great umbrage by the boldness with which he denounced the practice which prevails in Paris of personally soliciting those who have the disposal of scientific and academical positions. Candidates for such offices find that the necessity of paying visits to those who have votes or influence at their disposal is peremptory; for, great as the loss of time may be, and derogatory as may be the occupation, no candidate who refused such drudgery would stand the remotest chance of success. This applies to the highest as well as the humblest grades, for whether it be a simple *internat* or a professorship that may lead to world-wide celebrity that is sought for, election into a scientific academy, or the decoration of the button-hole with the coveted piece of ribbon—all demand the practice of a system of repeated and assiduous visiting. "Since 1835," says M. Verneuil, "Robert kept an account of all the visits he had been compelled to make in order to secure his success in his various candidatures, and these amounted to about 1,400. And surely never did statistics expose a more crying abuse! These 1,400 visits, taken one with another, must have each occupied an hour; and as few persons can consecrate more than four hours per diem for effective work, here we have a whole year lost in running about—a period amply sufficient for the preparation of a work capable of honourably transmitting a name to posterity." He stigmatises this abuse because he thinks utility may spring from so doing, "for what to-day seems but an utopia, to-morrow becomes a natural reform." It is evident that if the Continental *savants* obtain more honorific notices of their merits than with us, they have to go through a great deal of hard and excessively disagreeable work to obtain them; for not only have these visits to be made, but favours have to be asked, susceptibilities humoured, weak points discovered, and dignity compromised in a variety of ways.—'Medical Times and Gazette.'

CHLOROFORM.—It is, of course, not desirable to mention names so freely, but many journalistic errors are perpetuated by stereotyped fancies as to our "highest authorities." Dr. Johns is pleased to mention my name in a doubtful sense as having seen "about 300 cases of chloroform accident restored to life, or rescued after they had been pronounced dead." But my position, I would wish to explain, as hospital reporter for the 'Lancet' and other journals for a period of a dozen years, during nearly all which I attended twenty London hospital theatres, and saw from thirty-five to forty operations a week, under chloroform, or about two thousand every year, will explain the opportunities I have had of observing chloroform cases; and as to carrying a portable galvanic chain or battery in a great-coat pocket, it seems to astonish Dr. Johns, but it is as easily carried a a midwifery forceps or student's dissecting-case. Our giant hospital surgeons, our Astley Coopers, may have advised strong purgatives after hernia operations, and living surgeons, now at Guy's, turned chloroform into ridicule, and with M. Velpeau said anæsthesia was impossible; so of the early opinions of Dr. Gream. We must not, however, run after the mirage of great names once upon a time, but rather examine into actual facts of the present day.—Dr. KIDD, in 'Dublin Quarterly.'

CHLOROFORM IN AMERICA.—I need scarcely multiply authorities in favour of chloroform in the practice of midwifery. Meeting not long since my friend, Professor Simpson, of Edinburgh, at operations in London, I was pleased, on a very full comparing of notes, to find that he almost entirely agreed with the views adopted by me. We have had this year a report of our Medico-Chirurgical Society, the obstetric portion of which was confided to such experienced observers as Dr. Priestley, Dr. A. Farre, &c. That report speaks for itself. The study of the natural action of chloroform or ether, in fact, in hospitals and private practice, rather than imperfect statistics, can scarcely lead astray. A simple napkin, pinned into the shape of a cone, answers as an inhaler. "Chloroform and ether mixtures" are now beginning to be used, as pure chloroform is too sharp and strong; but for myself, as far as I can yet see, I would as soon order a blunt lancet or bistoury from an instrument maker. These ether mixtures are very tedious in their application; they have been supposed to be partial anæsthetics and not to enter the blood, but such a supposition is entirely fabulous, and in large surgical operations they cause a tendency to sinking and collapse immediately after the operation: it will be found, in fact, that the ether causes a species of common drunkenness, whereas pure chloroform, used in half-drachm doses, escapes quickly from the blood. In a memoir read within the last few months to the Academy at New York, the superiority of chloroform as compared to ether was generally admitted (though ether is the national and favourite anæsthetic in that country)—chloroform more especially in cases of rigid os uteri, eclampsia, and undilating perinæum. One speaker had given it in extensive heart disease, in patients of all ages, from the child of thirteen days up to persons of seventy; he had taken it himself about forty times. Another had given it in eighteen cases of forceps and fourteen of versional delivery; and he believed labour shortened, and made more safe by such means. Professor Martin, of Jena, as the result of one thousand cases under chloroform, confirms these views.—DR. KIDD, in 'Dublin Quarterly.'

SOCIAL SCIENCE ASSOCIATION.—This Association will hold its eighth annual meeting in the City of York, from the 22nd to the 29th of September, under the presidency of Lord Brougham. His Grace the Archbishop of York is one of the vice-presidents, and also the president of the Education Department. The Right Hon. Sir James Wilde, Judge of the Probate Court, presides over the Department of Jurisprudence. The other chairs had not yet been filled up. The Council of the Association have found it necessary, owing to the annual pressure of business, to adopt new regulations. In each of the departments, now reduced to four, three special questions are put, and a day is to be devoted to the discussion of each, the voluntary papers being read and discussed on the remaining days. The following are the questions in the Health Department:—1. What are the best means for disposing of the sewage of towns? 2. What are the causes, and what are the means for the prevention of, excessive infant mortality? 3. What is the influence on health of the overcrowding of dwelling-houses and workshops; and by what means could such overcrowding be prevented?

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ORIGIN AND NATURE OF SYPHILIS.

By Dr. Sisson.

Illogical conclusions, drawn from erroneous premises, and a slavish following of Astruc, have hitherto been stumbling-blocks to a proper elucidation of this subject; and what has been granted to other diseases of a like nature, has been altogether denied to this; consequently, notwithstanding all that has been written upon syphilis, the subject still remains in a state of chaos and confusion.

It is difficult, no doubt, to rid ourselves of preconceived ideas—

> "Quo semel est imbuta recens, servabit odorem
> Testa diu;"

yet, in order to approach the subject in a way likely to be attended with fruitful results, much that has been learned from books must be forgotten, and the over-refined and flimsy superstructure raised for syphilis upon the foundation of scholastic teachings (far more beautiful and masterly in design than useful for practical purposes), must be scattered to the winds, and a simpler and more solid fabric erected on the ruins.

The views of syphilographers are so often changing, that it is almost impossible to state correctly their opinions at any one time. If I have failed in this, the difficulty of the task must be my excuse.

Etymology of the Word.—The etymology of the word "syphilis" is unsettled. Mr. Herbert Mayo derives it from σιφλος, odiosam et invisam faciem habens, and accordingly adopts the spelling "siphilis," with an interpolation of the second syllable. Swediaur says: "The word 'syphilis' appears to me to be derived from the words συς porcus, and φιλια amor—as if we should say 'amor porcinus,' swinish love, filthy love, or a disease arising from impure coition." Such definition, however, is too imaginative, and seems to assign "illud detestabile crimen inter christianos non nominandum" as the prime cause of syphilis; an inference not warranted by authority.

We find the word "syphilis" thus spelt first used by Fracaster, in his poem entitled "Syphilis sive Morbus Gallicus," 1521, no doubt employed by him as a distinctive appellation for this the venereal disease *par excellence*, and derived simply from the words συν, and φιλια, love.

Introduction of Syphilis into Europe.—It would be a mere waste of time to cite all the old authors, from Hippocrates down to the year 1494, who, in treating of diseases of the genitals, have accurately described the primary and some of the secondary symptoms of syphilis; for the most strenuous opponents of the existence of this disease in Europe previous to the siege of Naples in that year admit this, but argue, nevertheless, that it was not syphilis to which these authors alluded, since they have not described *all the symptoms* of that disease which we now recognise. As we proceed, however, I hope to show valid reasons for such omission.

Astruc, who wrote in 1736 "De Morbis Venereis," and subsequent writers, adopting his opinion, have attributed the introduction of syphilis into Europe in 1493-4, and its propagation afterwards at the siege of Naples, to the followers of Columbus. In the Lettsomian Lectures "On Syphilis," delivered in 1858, before the Medical Society of London, Mr. De Meric exonerates the followers of Columbus, but inclines to the opinion that the disease originated at the siege of Naples, from the connection of a glandered individual with some of the loose females hovering around armies and suffering from simple ulceration. It is well known, however, that with the march of armies into foreign countries aggravated outbreaks of syphilis have frequently occurred, and have been attributed partly to the transmission of the disease from the natives of one country to those of another, and partly to the state of health of the recipients. Why, then, should we deny the possibility of such an occurrence at the siege of Naples, and its existence in a mitigated form previously? Moreover, it is probable that, in such an outbreak, the primary would be so speedily followed by constitutional symptoms, that their connexion, previously overlooked, could not fail to be recognised. And under any circumstances, it is no more remarkable that such recognition should have then first taken place, than that the distinction between scarlet fever and measles should not have been recognised in this country till about two centuries ago.

The same remark also applies to croup, concerning which a late writer says:—"It has often excited much surprise that a disease so distinctly marked in its symptoms should not have been accurately described before the middle of the eighteenth century, when Dr. Francis Hone published a treatise "On the Suffocatio Stridula," in 1765.—(Aitken's 'Practice of Medicine.')

Further, Mr. De Meric himself makes these pertinent remarks:—"We now meet in hospital and private practice with all the symptoms of syphilis which have been described by the writers of the sixteenth century; nay, we are more complete than our forefathers, as may be learnt from their works; for it is only by degrees and by successive authors that loss of hair, ulcers of the tonsils, affections of the bones and of the testes, were mentioned. *These manifestations of syphilis either did not appear at once, or their relation with the syphilitic poison was only gradually discovered.*"—(Lettsomian Lectures.)

Since, then, the semeiology of syphilis is allowed to have been very imperfect in the sixteenth century, it is reasonable to infer that at an earlier date it must have been more so. It appears to me, therefore, not less irrational than illogical to question the existence of syphilis before the year 1494, simply because before that time we have no perfect description of the disease.

As scarlet fever and measles were long confounded, so it is probable were syphilis and leprosy; and we find a writer in the 'Philosophical Transactions' for 1731-2 advocating such an opinion. "Local venereal affections," says Mr. W. Becket, "of a contagious nature had been known in Europe long before the year 1500; while under the vague name of leprosy a state of disease prevailed which, in many of its features, corresponded with lues. The former was likewise believed to be communicable through intercourse of the sexes." Mr. Becket believes it possible that syphilis may have lurked amongst the diseases grouped together as leprous, its connection with the recognised local venereal affections being overlooked; and this opinion seems borne out by the following passage from Peter Martyr's letter to Lusitanus, in 1488, in which he alludes to a supposed new disease:—"Qui appellatione Hispanâ Bubarum dicitur; ab Italis, Morbus Gallicus; Medicorum Elephantium alii, alii aliter appellant."

It is evident, then, to any unprejudiced mind, that syphilis existed, under a variety of names, long before the siege of Naples, in 1494; but so warped have been the opinions of syphilographers by their zeal for the authority of Astruc, that one and all, with few exceptions, have pertinaciously stuck to this siege of Naples fable. That it is a fable is evident, from the following statement of Mr. Bacot:—"As early as 1488, Peter Martyr, who was physician to the King of Spain, writing to Arius Lusitanus, the Greek professor of Salamanca, adverts to the new disease of their times, and specifies the "membrorum hebetudinem, juncturarum omnium dolores, ulcerum et oris fœditatem," which accompany it. Now, the same physician was at Barcelona when Columbus made his appearance there after his first voyage; but he does not say a word about the importation of the disease in any of his writings. Neither (continues Mr. Bacot) does Columbus, nor his son Ferdinand, who wrote the history of his father's life, in which he gives a description of all the diseases which afflicted the Spanish adventurers up to 1495" (Mayo 'On Syphilis').

Mr. Mayo adds: "If there is truth in this testimony, it seems to prove that siphilis existed, and had become partially known, before the commonly-supposed era of its origin."

Many of Astruc's cotemporaries, as well as previous writers, maintained that in the epidemics of Hippocrates were to be found unmistakable allusions to syphilis. Whether this opinion was well founded or not, Astruc's arguments against it are certainly invalid:—"Quod si remotis præjudiciis consulantur loca ipsa indicata, liquebit inde luce meridiana clarius, Hippocratem ne somniasse quidem de lue venereâ, sed pestilentiam descripsisse. Morbi nempe, de quibus loquitur, acuti, epidemici, cum febre conjuncti. . . . Cum e contra lues venerea, chronica et sporadica sit, sine febre invadat et solo veneris usu propagetur. Adde morbos illos curatos fuisse vel sponte, quod lui venereæ non convenit, vel saltem methodo, quæ ad luis venereæ curationem plane inefficax esset."—(Astruc 'De Morbis Venereis,' cap. 2.)

(To be continued.)

SCIENTIFIC ARTICLES.

ON THE OPERATION OF ASTRINGENTS ON THE URINARY ORGANS.

Lewald has proved that small quantities of acetate of lead, given in Bright's disease, diminished the excretion of albumen by the kidneys; and he conjectured that in a healthy condition of those organs the quantity and constitution of the urine were changed by the use of lead. The observations of Mosler and Mettenheimer, made to determine this point, were conducted in the case of a person of twenty-six years of age, suffering from a somewhat advanced state of tuberculosis, for the arrest of which the acetate of lead had been administered. The functions of the kidney were normal, and the mode of living and the diet were carefully regulated and watched, and the proportion of urine and fæces was accurately ascertained every twenty-four hours. The period of the experiments was divided into five sections—namely, 1. Eight days of observation without the employment of any medicine. 2. Eight days during which 3 grains of acetate of lead were administered three times daily, and reached 72 grains altogether. 3. Eight days during which 3 grains of acetate of lead were given four times daily, amounting altogether to 96 grains. 4. Five days during which 3 grains of acetate of lead were given six times daily, amounting to 90 grains altogether; and 5. Eight days without any medicine. The following were the results of the experiments:—1. The weight of the body was not particularly reduced until the middle of the fourth period, when there was a diminution amounting to five or six pounds, probably owing, however, to an affection of the stomach, for the weight again increased when this affection was removed. 2. From the results of the experiments, it appeared that the acetate of lead limits the excretion of urine, even under normal conditions. In the first period, the quantity of this fluid amounted to 2128 cubic centimètres; in the second to 1805; in the third to 1979, and in the fourth to 1750. It is probable that this result is to be attributed to the astringent operation of the lead upon the vessels. 3. As to the influence of lead upon the specific gravity, the reaction, and the colour of the urine, the reaction remained always acid, the colour varied from yellow to reddish-yellow, and yellowish-red, and lastly to brownish-red, and the excretion of the solid constituents of the urine was diminished during the employment of the lead. 4. The excretion of urea was diminished during the use of the lead, reaching in the first period 39,941 grammes, in the third period 25,877, and in the fourth 24,308. The urea appeared to diminish in exact proportion to the quantity of lead administered. 5. The chloride of sodium and the sulphuric acid of the urine were diminished during the use of the lead, and in exact proportion to the greatest dose of the drug; but the proportion of sulphur was relatively more diminished than that of the chloride of sodium. Mosler and Mettenheimer propose the question as to the dose of lead which may be taken without injury. It is a well-established fact that large doses, not too long continued, are much less injurious than a longer use of small doses, and also that one individual is more liable to poisoning than another. In the case recorded, no remarkable disturbance was caused during the lead-treatment; but after the administration of 240 grains, appearances of poisoning were developed, and attained a rather high degree. They gradually disappeared, but less from the application of the usual antidotes than from the employment of abundant injections of warm water. The proportion of urine was during this time very much reduced. It may be remarked that the employment of the lead exercised a very favourable influence upon the tubercular affection.—DR. SEMPLE'S 'Report on Materia Medica and Therapeutics,' in the 'British and Foreign Medico-Chirurgical Review.'

HOSPITAL REPORTS.

KING'S COLLEGE.

DISEASES OF THE FEMUR.

(Continued from page 36.)

A sinus is nothing more than a fistulous ulcer, of which the sides are sometimes hard, dense, unyielding, and not unlike the appearance presented on its surface by an indolent sore; the hardness and density may amount to a semi-cartilaginous condition, which, at first occasioned by the non-union of this long and unhealthy ulcer, comes at length to be a positive hindrance to a junction of the sides by any uniting processes.

The walls of these sinuses are not, as they appear to be, lined with a kind of mucous membrane, but are merely composed of a number of imperfectly-formed granulations, which exude a thin ichorous matter, and which present the appearance of a mucous tissue.

The course and starting-point of these sinuses are matters of no little import, as by them we are guided to the exact seat of mischief, and are thus led to discover the condition of parts at that point whence the discharge emanates. If they originate in an abscess, we may be able to pass our probe along the track of the sinus into the sac of the abscess; but if dead bone lie at the bottom and be the cause of the flow of matter, we may not always be able to discover it, because in some instances there may intervene either healthy bone or a firm plastic material which will cover it in and prevent the contact of the searcher with the dry bone.

There are cases in which the probe will be unable to reach the cause of the sinus, and this may arise from the great tortuosity of the sinus itself, whereby the instrument cannot be got to traverse its channel.

In the form of coxalgia, of which we are speaking, the sinuses are for the most part in or about the upper part of the thigh, showing that the disease is caries of some part of the upper end of the femur rather than necrosis of the acetabulum, or other portion or portions of the pelvis.

Should our endeavours to procure a good and useful limb by means of anchylosis be crowned with success, there is no further need for interference; but should failure attend our efforts, then, as a last resort, we have it in our power to excise as much of the head of the femur as may be diseased.

The operation consists in the following steps:—The patient being placed under the influence of chloroform and upon the unaffected side, a T-shaped incision is made over the diseased extremity of the femur; the vertical cut must extend from above downwards, and for a distance of about six inches, or even more should the bone be diseased below the termination of that incision; while the horizontal cut must be made at about right angles with the former, and so as to traverse across the trochanter major. It may not, however, be necessary to make such extensive incisions as these; for, if the gluteal or upper femoral region be riddled with the apertures of sinuses and be undermined with the canals of the same, it will be sufficient to pass a

director down to the dead bone, and guided by this instrument, to open up the tissues till the bone be reached.

Having come down upon the bone, the soft tissues are all well cleared away from it and protected from any danger by means of retractors. In order to be able to effect isolation of the head and upper part of the femur from the surrounding parts, the entire leg must be adducted at the same time that it was well rotated inwards, and, by being pushed upwards, made to present itself prominently or to actually protrude through the wound made in the integuments. When we have discovered the exact amount of disease the saw is to be applied below the bone so affected ; in this—the femoral—form of morbus coxæ we shall generally find it requisite to remove all that part of the thigh-bone which is above the trochanter, and likewise to include that tuberosity, since its cancelli are in the majority of such cases infiltrated with the peculiar cheese-like matter of struma.

It must not be omitted, after the removal of the upper portion of the femur, to examine carefully that part of the bone which lay in immediate connection with the disease, lest it also be involved in the morbid action, and we, without knowing it, leave it in, only to perpetuate the evils we had hoped by our operation to have removed. If, then, specks of dead bone are detected, they should be gouged out and the bone around each speck be well scraped, not only to insure the complete removal of any piece or fragment of carious or necrosed bone, but also to excite the healthy osseous substance to increased and reparative action, and to the throwing out of healthy granulations.

The wound is now to be closed ; the limb brought into the straight position, and to be maintained in this position by the aid of the long splint, extension being made in the ordinary method, or by obtaining a purchase on the upper part of the opposite thigh, as is recommended by Mr. Fergusson.

By Mr. Erichsen the bracket thigh-splint is advised to be used, instead of that to which we have just made allusion.

History of the operation :— In the year 1821, the operation was performed by Mr. Anthony White ; as, however, it met with great opposition from the Profession generally, and more particularly from Sir Everard Home and other leading men, by whom it was considered to be worse than useless, it fell into disfavour, and consequently into disuse, till, in the year 1845, it was revived by Professor Fergusson, and established as a legitimate operation, by his energetic efforts, as well as by those of Henry Smith, Haynes Walton, Simon, Buchanan of Glasgow, and Jones of Jersey.

Mr. Hancock also has contributed the weight of his influence to the establishing of the operation.

The following words we quote from the work of Professor Fergusson :—"Even yet experience as to the results of this operation is so limited, that I can scarcely say more on the subject than express a belief that, in some instances of disease, and of gun-shot injury of the neck or head of the bone, such a proceeding might be of service."

The results of the operation :—

First, as concerns the preservation or loss of life, in immediate connection with the operation.

On this head we cannot take upon ourselves to speak with statistical correctness, since records of the operation are either wanting altogether or not advanced in sufficiently large numbers to warrant their citation in either confirmation or disapproval.

As far, however, as a computation can be made, it is allowable to state that by the performance of this procedure many lives have been saved. Indeed, when the surgeon determines upon this operation, it is not so much for the sake of saving a limb as for the purpose of preserving life ; because in the disease of this joint—the disease involving, it may be, the pelvic bones or the femur—the danger to life is imminent.

This is a consideration with which, in the case of excision of other joints, the mind of the surgeon is not influenced to so large an extent.

The results, then, as far as regards life and the preservation of the patient's limb, may, upon the whole, be set down as satisfactory.

There is now to be weighed the condition for use in which the limb is placed after the operation. And this is by no means unsatisfactory. True, there are shortening to the extent of about three inches, a loss of the power to abduct or to rotate the limb outwards, a certain amount of stiffness dependent upon the fixidity gained for the entire leg by the anchylosis—which, it is to be remarked in passing, is of the fibrous and not the osseous character. But these apparent ill consequences are of no moment and are unworthy of consideration, when we see and reflect upon the good obtained for the sufferer.

The shortening is not greater than is created by the luxation upon the dorsum of the ilium, and which is attendant upon the later stages of the disease ; the limb, though the power to abduct or to rotate it outwards be lost, can yet be adducted, and, with every facility, flexed upon the pelvis ; the stiffness is not so great as to hinder motion ; and though the entire member may be not as facile in its own immediate movements as that of the opposite side, yet are there great powers of motion, and diversity of the powers, gained by these increased and ready mobility of the lumbar vertebræ. The entire limb, after the lapse of some time, comes to be of excellent condition, of material use and value to the patient, and, being well nourished, answers every, or almost every, purpose for which it was originally intended.

Caries of the great trochanter sometimes occurs independently of any hip-joint affection.

The diagnosis can be made without much difficulty, by passing a probe through the sinuses down to the bone, which will then be ascertained to be diseased. The area of the disease may in this manner likewise be detected.

The method of examination which we would adopt for the discovering of disease of the hip-joint being put into practice, will show us that this point is not involved in the affection of which we now treat.

In the treatment of this disease of the femur the sinus or sinuses leading to the bone should be opened up, the bone reached, and as much gouged away as may be found to be diseased. If the morbid action has extended itself into the interior of the head of the femur, the bones so implicated should be removed most carefully, in order that the joint may not subsequently become engaged.

In our manipulations we must remember how close we are to the joint, and must observe the greatest possible caution, lest we open into the interior of the capsular ligament, and so inflict upon the joint itself an injury which it would be almost beyond our power to make reparable.

The abscesses may point anteriorly, though they may have commenced posteriorly ; or they may burrow under the tensor vaginæ femoris, and then burst just below the attachment of that muscle to the facial covering of the thigh ; or they may pour their contents posteriorly and appear on the buttock ; or, again, they may traverse down along the fascia lata, and then open about the knee-joint or in some other place of the leg below that articulation.

Perhaps the most common situation of these abscesses is under the gluteal muscles. But wheresoever they may be present they have the effect of altering the action of muscles by stimulating them—in the same manner as would any foreign body—or parts of them to increased or unwonted action. Hence the change in the positions of the limb as the disease advances, and to which we have already made reference.

These abscesses, no matter where they may point, should be opened early and free vent given for the matter ; but it may burrow very extensively and so destroy the cellulo-areolar tissue, which is placed between the several planes of muscles.

It is not usual in the femoral variety of morbus coxæ to have pelvic abscesses form ; when, indeed, such an occurrence takes place, we may suspect either that the disease of the femur has involved the acetabulum, or that the pelvic bones are themselves the true situation of the affection, there being no involving of the bone of the thigh.

Another of the sequelæ of the affection upon which we are treating is the establishing of unhealthy sinuous openings leading from the interior of abscesses or from the place where a fragment of dead bone is lying, and by its presence occasioning more or less irritation and the keeping up of an unhealthy discharge.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XXI.

COLLODIUM AND PYROXYLIN.—Following the alphabetical order we have adopted, we come next to collodium; but it will be convenient first to mention the substance the solution of which in ether and alcohol constitutes collodium. *Pyroxylin*, or gun-cotton, is made by immersing cotton in a mixture of sulphuric and nitric acids. When this is done, a peculiar change is effected in the cotton, the exact nature of which depends upon the strength of the nitric acid employed. It must be stated that the only object of using sulphuric acid is to withdraw water from the nitric acid; further than that, the sulphuric acid does not affect the reaction.

To render intelligible the change which takes place, we must explain that the formula ascribed by chemists to cotton or cellulose is $C_{12} H_{10} O_{10}$. When the cotton is immersed in nitric acid ($N O_5$) three of these atoms are condensed into one—$3 (C_{12} H_{10} O_{10}) = C_{36} H_{30} O_{30}$, and, according to the strength of the acid, a variable proportion of hydrogen is removed, and replaced by an equal number of atoms of hyponitric acid ($N O_4$), the hydrogen displaced forming water with the surplus oxygen.

The Pharmacopœia, it must be remembered, makes use of the strongest nitric acid (sp. gr. 1·5); and when this is employed nine atoms of hydrogen are replaced by the same number of atoms of hyponitric acid, and thus is obtained what may be called the highest form of pyroxylin, to which the scientific name *tri-nitro-cellulose* has been assigned. The change will be explained by the following equation:—

$$C_{36} H_{30} O_{30} + 9 N O_5 = \left.\begin{matrix} C_{36} H_{21} \\ 9 N O_4 \end{matrix}\right\} O_{30} + 9 H O.$$

This, as we have said, is the change which takes place when the strongest nitric acid is used. But it will be seen that the formula of pyroxylin given in the Pharmacopœia is—

$$\left.\begin{matrix} C_{36} H_{22} \\ 8 N O_4 \end{matrix}\right\} O_{30}$$

a fact which requires a short explanation. The directions for the preparation of pyroxylin were supplied by an English member of the Pharmacopœia committee, under the belief that the nitric acid of the British would be of the same density as that of the London Pharmacopœia—1·42. Later, however, it was decided to adopt the stronger acid; but the formula for pyroxylin was forgotten when the change was made. Now tri-nitro-cellulose (the most explosive form of gun-cotton), which is made by the Pharmacopœia process, is insoluble in ether, and is consequently inapplicable to the preparation of collodium, and moreover, as we have shown, has not the composition represented in the Pharmacopœia. The difficulty, however, is all removed by employing nitric acid of the density 1·42, which, indeed, is specified in the smaller and later edition of the Pharmacopœia. When this is used, a pyroxylin of the composition assigned is obtained, which is soluble in ether. Strictly speaking, this may not be correct, for only seven or six atoms of hydrogen may be displaced; but this is of no consequence, since all the lower and less explosive forms of pyroxylin are soluble in ether.

Gun-cotton was probably first made by Braconnot in 1833, but it is usually said to have been discovered by Schönbein in 1845. One of the first, if not the very first (in 1848), who noticed the fact of its solubility in ether was Dr. Bigelow, an American practitioner, who certainly was the first to employ such a solution in surgery. Since then the use of the solution, under the name of collodion, has greatly extended, and it now appropriately finds a place in the British Pharmacopœia.

As most practitioners will make their own gun-cotton and collodium, we give the respective formulæ, in a few words:—

Pyroxylin.

Take of Cotton, an ounce;
Sulphuric acid, five fluid ounces;
Nitric acid, sp. gr. 1·42, five fluid ounces.

Mix the acids and immerse the cotton for three minutes, continually stirring the mixture. Afterwards well wash the cotton, and dry over a water bath. The exact time th cotton is immersed is of no great moment, so that it is not less than three minutes. The washing must be continued until all trace of acid is removed.

Collodium.

Take of Pyroxylin, one ounce;
Ether, thirty-six fluid ounces;
Rectified spirit, twelve fluid ounces.

Mix the ether and spirit, and add the pyroxylin.

When collodium is applied, the pellicle contracts as it dries, and causes a puckering of the skin, which is a great objection to its use in some surgical cases. We may therefore mention that an elastic collodion which does not contract may be made by adding to the Pharmacopœia compound about one-sixth of its bulk of castor-oil or Venice turpentine. The addition of mastic has also been found to give strength and durability to the pellicle. An excellent blistering collodium may also be made by dissolving four or five grains of cantharidin in an ounce of the Pharmacopœia preparation. Lastly, collodium has been employed as a vehicle for the application of bichloride of mercury and iodine in some skin diseases.

CREASOTUM.—No directions for the preparation of creosote are given in the Pharmacopœia, and the authors have wisely abstained from giving any further account of it beyond what is contained in the words "a product of the distillation of wood tar." The exact process by which creosote is obtained from tar is kept secret by the best manufacturers in this country; but it no doubt essentially consists in the repeated rectification of the products of distillation, the solution of the impure creosote in caustic potash, the subsequent decomposition of the solution by sulphuric acid, and the redistillation of the creosote. This latter part of the process is repeated several times, until the product is obtained colourless.

The creosote so procured from *wood tar* is a mixture of several bodies, among which phenylic and cresylic alcohols are said to predominate.

A similar process carried on with *coal tar* furnishes principally phenylic or carbolic acid, a definite body quite distinct from that intended by the Pharmacopœia.

The creosote imported from Germany is distilled from coal tar, and consists chiefly of carbolic acid; that sold by the best English makers is distilled from Stockholm tar, and contains but little carbolic acid. In odour and appearance the two articles closely resemble each other.

The tests given in the Pharmacopœia are, first, the specific gravity, which should be 1·065. Any admixture of alcohol, or a fixed oil, would, of course, lower the gravity, and the latter adulteration would also be indicated by the translucent stain left, if the creosote were dropped on filtering paper, and exposed to a heat of 212°. The other tests afford no peculiar indications of the quality of the creosote.

MISTURA CREASOTI.—In making this mixture, the Pharmacopœia orders the creosote to be dissolved in glacial acetic acid; but as creosote is only soluble in strong acetic acid, it separates again as soon as the water is added.

CUPRI SULPHAS.—Sulphate of copper calls for but a short notice. The commercial salt is directed to be purified by recrystallization. The most common contamination is

iron, the presence of which will be detected by ammonia. If the sulphate of copper is free from iron, whatever is precipitated by ammonia will be redissolved by an excess of the precipitant, forming a clear sapphire-blue solution.

PARISIAN MEDICAL NEWS.

HOSPITAL DE LA CHARITE.

M. BEAU ON HÆMOPTYSIS—EFFICACY OF PRESSURE AND FARADISATION IN MONO-ARTICULAR RHEUMATISM.

M. Beau recently invited the attention of his class to bilious hæmoptysis, a symptom which, in his opinion, has not hitherto received all the notice it deserves, and which unmistakably occurred in a case at present in the wards. The patient was a woman affected with copious hæmoptysis, coincident with a bitter taste in the mouth and vomiting of bile. In accordance with the precepts laid down by Stoll, M. Beau at once prescribed the following emetic :

℞ Pulv. ipecac. gr. xv. ;
Antimon. tartarati, gr. ij. ;
Aquæ, ℥v.

To be taken in two doses at an interval of ten minutes. The object of the association of tartar-emetic and ipecacuanha is to secure the emetic action of the remedy ; either drug, separately administered, sometimes fails in producing the desired effect, which, on the contrary, is induced with certainty when both are simultaneously exhibited. In the present instance, a large amount of bilious matter was soon ejected, and the spitting of blood was immediately checked.

Bilious hæmoptysis may be idiopathic, but this is seldom the case. In general, the spitting of blood is connected with chronic tuberculosis revived by the coincidence of gastric disturbance, and giving rise to a form of hæmoptysis which deserves the denomination of bilious, an appellation fully justified by the immediate effects of the emetic. M. Beau disclaims all belief in the alleged astringent and hæmostatic virtues of ipecacuanha ; the very short period during which this powder is retained by the stomach shows that it must be considered merely in the light of an evacuant ; and if the drug has been found beneficial in dysentery, the fact must be ascribed to the removal by its agency of a bilious condition of the *primæ viæ*. It is for the same purpose that the Professor exhibits ipecacuanha to persons affected with tuberculosis, in whom it effects a degree of improvement so marked as sometimes to lead to an entire recovery.

Another suggestive and interesting case of hæmoptysis was observed at the same time in the wards.

The patient was a woman who had been admitted into hospital awaiting her confinement, and who also had several attacks of hæmoptysis, which M. Beau hesitated to ascribe to pulmonary tuberculosis, on account of the infrequency of the progress of phthisis during pregnancy. The only physical signs discoverable on auscultation were the sonorous rhonchi characteristic of bronchitis, and the spitting of blood was clearly symptomatic of a congestive state of the lung consequent on gestation. Visceral congestion is a circumstance which often coincides with gravidity, and which may occasion various symptoms ; the abstraction of a small amount of blood is then a useful palliative measure. Labour may be relied on to restore the system to its natural condition, and to effect a complete cure.

Most readers are acquainted with the rules laid down by M. Beau for the management of rheumatic fever. We shall perhaps revert to this important subject on some future occasion, but we shall for the present confine ourselves to a reproduction of the Professor's remarks on circumscribed articular rheumatism, a disease which occupies an ill-defined place in medical classifications, and is designated by the terms rheumatic arthritis, mono-articular rheumatism, &c. This affection bears an indisputable analogy to articular rheumatism ; it is, for instance, generally referable to the same cause, viz., exposure to wet and cold, and is attended with severe pain. On the other hand the absence or mildness of the concomitant fever, the tenacity of the inflammatory action which is fixed in one joint, the loss or diminution of the power of motion, and the subsequent tendency to the formation of white swellings, are circumstances which distinguish mono-articular arthritis from common rheumatism.

The joints of the hand or foot are those which are most liable to be invaded. In one of M. Beau's patients the left wrist alone is affected, and the treatment adopted by the Professor has led to results which are deserving of every attention.

The measures resorted to consisted in the application of pressure and of Faradisation.

The object of pressure is to subdue the symptoms of the first stage of the malady, viz., the inflammatory pain and swelling ; the electric action is intended to effect a cure of the subsequent plastic engorgement.

The pressure is applied with strips of adhesive plaster. It sometimes induces pain at first, but this soon decreases and the swelling subsides. The practitioner must, however, not be disappointed if these symptoms reappear, and necessitate a removal of the adhesive plaster. The relief is immediate, but variable in duration ; and when the pain returns with any degree of intensity, pressure must again be instituted, and its sedative effects will now be much more apparent. Two applications are in general sufficient, but a third resort to the same method is sometimes desirable if the pain proves obstinate. A complete cure is thus usually effected.

In the patient who suggested these remarks, these singular alternations of improvement and relapse were observed, but with a gradual and perceptible abatement of the intensity of the symptoms. In this case the disease yielded only after three successive applications of the compressive strips of plaster, in the course of as many weeks. On each occasion the pressure relieved the pain, and restored sleep ; the inflammatory action then returned, but with decreased violence, and finally ceased after the third dressing of the wrist.

Despite its favourable results, this course of treatment would have been insufficient, had not M. Beau resorted to another series of remedial measures calculated to remove the articular swelling which persists after the cure of the acute symptoms, and which it is of the greatest importance to subdue. We allude to Faradisation. In the present case the joint was so swelled that the hand and fingers were utterly immovable. Twice a day sponges moistened in water and secured to the directors of a magneto-electric machine were passed over the articulations,— a method to which M. Beau ascribes far more effectual resolutive powers than can be obtained by any other remedial agent. The electricity is thus conveyed through every part of the diseased structures. The manipulation of the instrument is soon acquired ; and although at first the patients often object to its use, they soon become reconciled to a procedure which affords such prompt relief.

Faradisation was daily applied for a month in the case above noticed. The patient was recommended to clothe herself warmly in the intervals of the operations ; and although she frequently neglected this advice, the swellings rapidly and gradually disappeared, and the hand and fingers recovered full liberty of action. In short, pressure first relieved the pain, and electricity dispelled all fear of subsequent disease of the joint.

We may, in concluding, remark that this is not a solitary instance of the good effects of the medication instituted in similar cases by M. Beau. This gentleman has obtained many equally satisfactory results from this method, and he now unhesitatingly resorts to Faradisation for the cure of articular disease of long standing. He expresses a confident hope that a knowledge of the great resolutive power of magnetic electricity must lead to a more frequent and extensive recourse to this agent, for the cure of a host of chronic affections which have hitherto yielded only to protracted and wearying measures of treatment.—'Journal of Practical Medicine and Surgery.'

EFFICACY OF THE WATERS OF MONT DORE IN CONSUMPTION.

A debate recently occurred at the Society of Hydrology, on a subject brought forward by M. Mascarel. This gentleman practises in summer at Mont Dore, and forwarded some time since to the Society a paper, entitled 'A New Inquiry on the Curative Powers of the Waters of Mont Dore in Tubercular Consumption.' This memoir gave rise to the discussion now briefly alluded to.

The author is a firm believer in the curability of tuberculosis in every stage, and brings forward in support of this view a series of cases collected by himself at Mont Dore and witnessed by MM. Bouillaud, Mélier, Bouchut, Guérineau, Horteloup, &c., and vouched for by M. Desnos, the reporter, as presenting the most satisfactory scientific characters.

Comparing the respective effects of the waters of Ems and of the Pyrenees with those of the springs of Mont Dore in tuberculosis, M. Mascarel explains the superiority of the latter by their much less marked tendency to induce hæmoptysis.

His opinion obtained the all but unanimous assent of the Society, and met with opposition from one member only, M. Pidoux. Notwithstanding our sincere respect for this gentleman's attainments, we must remark that, in this circumstance as in his recent publications on the subject of phthisis, the Inspector of Eaux-Bonnes appears to us to dispose with much too unceremonious a tone of superiority of the conscientious researches of deserving fellow-practitioners.

The facts adduced by M. Mascarel are sufficiently conclusive to invite attention, and M. Hérard expressed himself to that effect. They indisputably prove that the waters of Mont Dore, unlike sulphurous springs, allay pulmonary congestion, and are, therefore, in this respect, preferable, as we have for some time suspected, to the spas of Ems and of the Pyrenees.—'Journ. of Prac. Med. and Surg.'

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

The number commences with Mr. G. JOHNSON'S second lecture, delivered before the College of Physicians, "On the Laryngoscope." He shows, by a series of illustrative cases, the use of this instrument in distinguishing the various affections of the larynx, and also in proving, by negative evidence, the existence of disease in other parts causing laryngeal symptoms. Thus, for instance, a person was treated for laryngitis, before the invention of the laryngoscope, and, on a post-mortem examination, the larynx was found quite healthy, and the cause of the symptoms was discovered to be a cancerous tumour, filling up the arch of the aorta, and involving the branches of the pneumo-gastric nerve. In another case, apparently of acute laryngitis, laryngoscopic investigation proved that the larynx was healthy, and it was suspected (what afterwards turned out to be the fact) that there was an aneurism of the aorta. In some cases, again, laryngitis is simulated by hysterical patients, in whom no inflammation exists; and, on the other hand, patients, apparently hysterical, have been found to be really labouring under congestion, or inflammation of the larynx. Different forms of syphilitic laryngitis are also detected by means of the instrument, and a guide is thus afforded to appropriate treatment.——Dr. HUMPHRY, of Cambridge, under the head of "Surgical Observations," continues his remarks on Lithotomy, and describes the effects of stone upon the bladder and the system, and shows that large stones are unattended with much suffering or disease. It appears that in process of time the bladder becomes inured to the irritant, and although small stones usually produce great irritation, large ones are often retained in the bladder for many years without inconvenience. It has been supposed that the use of chemical solvents taken into the system has the effect of lessening the size of the stone; but this does not appear to be the case, although these agents may diminish the sufferings of the patient. It appears, in fact, that alkaline remedies do not even always prevent the addition of lithic acid to a stone already formed.——Dr. HYDE SALTER concludes his paper "On Tracheal Dysphagia," and after giving two more cases of the successful management of this affection, he sums up by describing its nature and treatment. He shows that the inconvenience is caused by some irritation or inflammation of the larynx or trachea, that it is a transient affection, and terminates favourably. The dysphagia is less when the chin is bent down than when it is raised, because in the former case the trachea is less stretched. The treatment should be adapted to relieve the symptoms by measures calculated to remove tracheal inflammation, such as sedatives, counter-irritants, rest warmth, &c.——Mr. W. H. FOLKER relates "A Case of Femoral Aneurism, successfully treated by Ligature of the External Iliac." The aneurism appeared to arise spontaneously; and as it was retarded, but not stopped in its growth, by rest and cold applications, it was determined to operate. The convalescence was satisfactory, except that suppuration took place in the sac, and an abscess formed, which, however, burst spontaneously, and the cure was afterwards uninterrupted. As the suppuration was circumscribed, it was thought better not to resort to incisions.——Dr. P. GORDON STEWART relates "A Case of Traumatic Tetanus occurring in a Negro, and followed by Recovery." The affection was traumatic, and the symptoms were very severe. Several remedies were employed, as chloroform, croton oil, calomel, and compound jalap powder, and the spine was vesicated and afterwards dressed with mercurial ointment. Dr. Stewart does not know exactly to which remedy the cure is to be attributed.

'MEDICAL TIMES AND GAZETTE.'

The number of the 'Medical Times and Gazette' which we now review begins with the first of three clinical lectures "On Iridectomy and Glaucoma," by Mr. WHARTON JONES, of University Hospital. The operation—iridectomy—is explained as meaning excision of a portion of the iris, and it is shown to be *central* or *lateral* in the method of performance. The object is to form an artificial pupil; so that when the cornea immediately in front of the pupil is opaque, light may be admitted upon the retina and at least a certain amount of vision gained. Clearance of the cornea is centrifugal. The conditions of the iris and pupil in cases of perforating ulcer of the cornea are mentioned. Lateral excision is the more usual, and is done not only in the instance just mentioned, but also when the pupil is occluded with lymph and by adhesions. The

operation is as follows :—The patient lies upon his back, with his head raised and fixed ; chloroform may or may not be administered ; the lids are separated ; the cornea incised where we would have it perforated—namely, near and concentric with its margin—the opening being made by means of a cataract knife, and according to the plan of puncturation and counter-puncturation ; the aqueous humour flows away, and at this stage the iris may become prolapsed, unless adhesions be present to prevent such an occurrence : when it happens, the projecting iris is to be snipped off. Should the iris, however, not protrude, owing to its being bound down by adhesions, it must be seized by the forceps and drawn out to the necessary extent ; at the same time, great care must be taken not to wound the capsule of the lens. Little or no bleeding takes place from the cut iris, unless it be in some way unsound. The object of the operation is to evacute aqueous humour so as to allow the vitreous body and lens to press against the iris and cause it in turn to press against the cornea. The corneal wound quickly unites, and the eyeball regains its natural rotundity. The aqueous humour is stated to be derived from the blood of the ciliary processes, and not from the lining membrane of the aqueous chambers, nor from the iris. In cases of irideremia there is nevertheless abundance of aqueous humour. Blood effused into the chambers of the eye is rapidly effused. Evacuation of aqueous humour, as introduced by Mr. Wardrop for dim vision, the result of hypersecretion of that humour, is commented on, and shown to be highly useful and most valuable as an auxiliary to medicinal treatment. Glaucoma is defined to be a diminution of sight, or an entire loss of the sense, with an alteration in the pupil, and a peculiar sea-green opacity at the back of it. The derivation of the word is from γλαυκος, sea-green. The peculiar opacity of this affection has been proved by Dr. Mackenzie to be dependent upon an alteration in the lens, which body, though transparent, reflects much of the light thrown upon it. This coloration is shown to be merely incidental, and not a pathognomonic sign of the disorder, and is often found existing in old persons who are free from all ophthalmic diseases. Great general venous congestion of the eye, but especially of the choroid and retina, is the essential characteristic of glaucoma, the humours being all transparent ; the arteries, owing to venous compression, are slender and pale. The conditions of the other structures of the eye, viz., of the choroid, the external veins, the iris, the humours, and of the lens, are severally pointed out.——Dr. HARLEY continues his lectures "On the Urine and Urinary Organs," hippuric acid being the subject selected for consideration, and discussed in its chemical, physiological, and pathological bearings. Having passed this in review, he then directs attention to the chloride of sodium or common salt. ——Dr. THOROGOOD communicates a paper in which is shown the curative effect of "Belladonna in Certain Forms of Epilepsy."——Dr. COGHLAN contributes "Notes on Dysmenorrhœa and Sterility."——Drs. JACKSON and BULLEN have articles, the former "On Amaurosis with Hemiplegia ;" the latter, "On the Removal of a Large Neuroma from the Median Nerve."——"The Action of the Bromide of Potassium" is the subject of a paper sent in by Dr. WILLIAMS. In this he shows the benefit to be obtained from the medicine in cases of epileptic convulsions.

REVIEW OF BOOKS.

Exanthematous Diseases : their Rational Pathology and Successful Treatment. To which are added, Remarks on Hooping-cough, Diphtheria, Croup, Laryngismus Stridulus, Chorea, and Erysipelas. Illustrated by Details of Numerous Cases. By John Pursell, M.D., F.R.C.S.E. Pp. 103. London : Churchill and Sons. 1864.

The principal object of Dr. Pursell in writing this little book appears to be to show the efficacy of quinine or cinchonine in the treatment of the diseases mentioned in the title-page ; and the use of these alkaloids was suggested to his mind by the remittent character which he states he had generally observed those maladies to assume. In his description of the symptoms of the diseases mentioned, and of their varieties, it does not appear to us that Dr. Pursell has exhibited much originality, or has introduced any novelty ; and in some instances—as, for example, in describing diphtheria and croup—he does not seem to have made himself thoroughly acquainted with the recent literature of those subjects. Again, that most of the exanthematous affections exhibit a certain periodicity in their course is quite true, but we are not sure that their remittent character is so striking as Dr. Pursell would represent ; and therefore we can scarcely agree with him in the peculiar efficacy of the cinchona alkaloids in their treatment. The general application of tonic and supporting measures in such diseases is, however, no doubt beneficial.

On Poisoning by Diseased Pork. Being an Essay on Trichinosis, or Flesh-worm Disease : its Prevention and Cure. By Julius Althaus, M.D., M.R.C.P. Lond. ; Physician to the Royal Infirmary for Diseases of the Chest. Pp. 34. London : Churchill and Sons. 1864.

The substance of this essay has already appeared in the pages of a medical contemporary, and we have previously noticed the chief points brought forward by the author on the very important subject of trichinosis. Since the appearance of the original papers and the publication of the present essay, Dr. Althaus has made several additions, in consequence of the development of new facts in connection with the trichina disease. We consider Dr. Althaus's essay, in its present form, to be the best monograph which has hitherto appeared on the subject of trichinosis.

MR. BAKER BROWN'S services to science and practice have lately received a new recognition on the continent. The Société des Sciences Médicales et Naturelles of Brussels has lately conferred on Mr. Brown the title of corresponding member, the diploma being accompanied by an extremely flattering letter from the President of the Society.

THE LATE APPOINTMENT OF APOTHECARY IN DROGHEDA WORKHOUSE.—The name of the gentleman who was appointed apothecary in the Drogheda Workhouse at the last meeting of the Guardians is M'Greevy, not M'Creedy, as erroneously printed in this Journal last Saturday. Surgeon M'Greevy is highly respected both in Antrim and Lurgan, where he has heretofore resided. So long ago as 1857 the inhabitants of Antrim presented him with a valuable gold watch and chain and a purse of sovereigns for his unwearied attention to his professional duties and his self-sacrificing devotion during the awful visitation of the scourge of cholera amongst the poor of that town. We have no doubt Surgeon M'Greevy will give every satisfaction in his new sphere of labour, and fully sustain the high opinion the Guardians here have formed of him.—'Drogheda Reporter.'

THE MEDICAL CIRCULAR.

WEDNESDAY, JULY 27, 1864.

HOMŒOPATHIC STATISTICS.

It has sometimes been said, and with considerable truth, that statistics may be made to prove anything. You have only to exclude some class of cases which might tell against you, or include others which may tell in your favour, and afterwards do as you like with the rest, and then your statistics are ready for use. One of the most amusing specimens of this kind of statistical cookery which has lately fallen under our notice is a Report of the Leopoldstadt Homœopathic Hospital at Vienna, for the year 1861—a document which is admirably calculated to effect the purpose for which it was no doubt designed—namely, to gull the public. The names of all the diseases, on the principle *omne ignotum pro magnifico*, are given in Latin: thus, hiccup is singultus; gum-boil is parulis; chilblains are perniones; mumps are parotitis, &c.; and although these and other diseases of a similar kind are not particularly important or severe, it appears that the cases are all treated as in-patients, and the period of their stay in the hospital is accurately measured.

The mortality at this establishment is so wonderfully low, that we are surprised that any people ever die at Vienna; and, indeed, if the success of homœopathic practice should continue to be so great at the city in question, Rokitansky and other morbid anatomists who have hitherto made their post-mortem examinations by the thousands every year, will soon find that their "occupation's gone," and that there are no bodies for them to dissect. Out of 818 patients at the Leopoldstadt Homœopathic Hospital, only 17 died, being in the proportion of about 2 per cent., a result which is perfectly astounding as compared with the mortality at other establishments. The time occupied in the treatment of the above patients amounted to 13,013 days, giving for each patient an average of 15·9 days.

On examining these statistical tables more closely, we are led to admire the sanitary condition of Vienna, and at the same time to congratulate the inhabitants of the Austrian capital on their apparent immunity from those serious diseases which we know to prevail in other parts of the world. Disease does indeed occur, but the serious forms of it are comparatively unknown if we are to believe the tables before us, because we presume that the authorities of the hospital do not turn away from the door those cases which are acknowledged to be difficult and dangerous, but take them all as they come. We accordingly find among the 818 cases recorded, that there were only nine of tuberculosis of the lungs, of which only two died; only three of cancer, all of which recovered; only one of syphilis, which of course recovered; only one of apoplexy, which also recovered; one of meningitis, which likewise recovered; and only five of disease of the mitral valves, and even of these two were relieved.

On the other hand, we find that diseases not considered either serious or generally fatal by the Medical Profession figure very largely among these 818 cases treated as in-patients, and remaining under treatment for an average of 15·9 days. Thus, for instance, common colds, under the imposing names of catarrh. laryng. acut. and chron., catarrh. pulmon. acut. and chron., amount to fifty-seven cases, all of course terminating in recovery; common sore-throats, under the name of angina, amount to thirty-two cases; of gum-boils there are nine—exactly the same number as those of pulmonary consumption; common diarrhœa, under the names of catarrh. gastro-intest. and chron., affords no less than ninety-three cases; and amenorrhœa, and chlorosis, and dysmenorrhœa, account for forty-seven more. That some sort of selection is observed in the retention of the cases is very evident from the admitted fact, that nine cases of variola were sent away to another hospital—whether homœopathic or otherwise, we are not informed. This dismissal of the small-pox cases strikes us as rather unfair, because, if the principles of homœopathy are true and the practice successful, small-pox ought to be as amenable to treatment, and to afford the same proportion of extraordinary cures, as any other disease.

A large city which, out of 818 cases of disease, affords only nine of pulmonary phthisis, one of scarlatina (cured), three of cancer (all relieved), one of apoplexy (cured), one of meningitis (cured), two of white swelling (cured), must be in an enviable state of salubrity; and it may be assumed that in other forms of disease either the type of the malady was mild, or the treatment was almost miraculously successful; for, out of eighteen cases of peritonitis, only one died, and out of 154 cases of acute, subacute, and chronic rheumatism not one fatal case occurred! We are not, indeed, surprised that the case of hiccup (singultus) recovered under the use of the globules, and that the chilblains and the gum-boils were treated with equal success by the same method—aided, perhaps, by warmth and food in the one case, and probably by the gum-lancet in the other; but the cures in other cases really almost surpass belief: apoplexy is cured, meningitis is cured, white swelling is cured; while even cancer and valvular disease are relieved.

But on examining the details which have been furnished in reference to some of the cases, our incredulity is partly diminished. Thus, for instance, we are favoured with some particulars as to the case of apoplexy; and we find that the patient was a strong, stout woman, who was seized with temporary unconsciousness, and who was treated before she arrived at the hospital by *ice to the head and a strong purgative*. By the time she came to the hospital she had regained her consciousness, and the cure (?) is complacently attributed to the homœopathic inanities which she was directed to swallow when all dangerous or important symptoms had disappeared or were disappearing. We have sought in vain for any information of a detailed description, of any of the other wonderful cures, and the person who has drawn up the report is entirely silent as to the extraordinarily small proportion of phthisical cases, the diagnosis of the cancerous ones, the treatment of the cases of peritonitis, and many other points on which accurate information would be very desirable.

But, *en revanche*, the compiler details the particulars of the common colds, which we are told were very frequent, and all recovered under globulistic treatment; and we may very safely assert that if these fifty-seven cases, pompously described as pulmonary and laryngeal acute and chronic catarrh, had been put into a comfortable room, and had been subjected to no treatment at all, except an allowance of ordinary food and protection from the inclemency of the weather, they would all have equally recovered.

In many of the cases, therefore, we may be satisfied that the homœopathic treatment did no harm, and that it was equally immaterial to the result whether the patients took the decillionth of a grain of sugar, or flint, or chalk, or anything else of the same kind, and in the same doses. But we are not so sure that, on the showing of the homœopaths themselves, many of the cases were not cruelly neglected, and that the sufferings of the patients were not needlessly prolonged by the non-administration of suitable remedies. Thus, for instance, we are told that a poor girl was allowed to die of anæmia, in whose body, after death, nothing was found except a shrivelled, lax, and bloodless condition of most of the internal organs, and a few scars of ulcers in the ilium. She would probably have recovered under the use of iron, quinine, and nourishing food. Again, we are informed that there were thirteen cases of hemicrania (a form of neuralgia); and we are candidly told (*mirabile dictu!*) that not one was cured, and that *it was not often very easy to relieve the head-ache.* Very likely not by the homœopathic globules; but quinine or arsenic in proper doses would, in all probability, have relieved the sufferings of these unfortunate patients, who, we are told, left the hospital uncured, and who, we hope, were subsequently relieved of their pain by some practitioner who was uncontaminated by the homœopathic absurdities.

We have thus indicated pretty clearly what we think of the Report of the Vienna Homœopathic Hospital, which is probably a type of its kind, and is no worse and no than any other similar institution devoted to carrying out the views of Hahnemann.

SUMMARY OF THE WEEK.

THE BRITISH PHARMACOPŒIA.

As many statements, more or less erroneous, are current on the subject of the British Pharmacopœia, we think it right to repeat what we have on a former occasion observed, that there is no probability whatever that the present work will be withdrawn from circulation, and that those who expect the speedy appearance of a new book will inevitably be disappointed. The edition just sent forth is rapidly being disposed of, but fresh copies will be supplied as occasion requires; and the only step now being taken in reference to a new edition is the appointment of a committee, consisting of representatives in London, Edinburgh, and Dublin, to examine into the defects of the present work, with a view to a new edition at some future period. There is not the slightest chance that this new edition will appear under at least eighteen months from the present time, and it will then come just like any other second edition of a scientific work, corrected up to the time of its publication. We are no apologists for the British Pharmacopœia, and we have repeatedly exposed its defects and shortcomings in our pages; but, nevertheless, we are aware of the enormous difficulties of the task involved in the fusion of three Pharmacopœias into one, and we are disposed to be lenient to those who have had the management of so laborious a duty, which has required great tact and discretion, as well as the higher qualities of learning and experience. We could, if we chose, point out some of the individuals by whom the leading mistakes in the British Pharmacopœia have been perpetrated, and the obstinacy of a few, and the too ready acquiescence of others, by which objectionable features have been introduced. We shall, however, only remark in general, that national prejudices and prepossessions are hard to overcome, and to this cause many anomalies and incongruities are to be attributed; added to which, the book has been compiled by three committees, all sitting at once in different parts of the kingdom, and consequently unable to work in perfect harmony with each other. It may also be stated, that however eminent may be some of the members of the Medical Council, they are not all good chemists, and none of them are pharmaceutists; and some of the subordinates to whom they delegated their functions might not be, perhaps, the most competent assistants, or the least biassed by preconceived views. But all these difficulties were inseparable from the very idea of forming a National Pharmacopœia; and the present volume, imperfect as it undoubtedly is, is quite as good as could be reasonably expected when the enormous labour of smoothing existing inequalities and overcoming objections is taken into account.

THE COLLEGE OF PHYSICIANS AND THE GOLDEN APPLE.

About the year 1815, the three London Medical Corporations were somewhat in the position of the three goddesses, who exhibited their charms in emulous rivalry to the Royal Shepherd of Mount Ida; but unlike Minerva, Juno, and Venus, who all coveted the glittering prize, the College of Physicians, the College of Surgeons, and the Society of Apothecaries were indifferent to the bauble in the shape of the Apothecaries' Act, and the two former positively declined it; and it was at last pressed upon the latter body by the Government of the day. It must be admitted that the apple at that period was not worth much, and instead of being a ripe golden pippin, it was both sour and immature. Since then, however, it has increased in bulk and in flavour, and consequently in value; and now that the fruit has become completely ripe, the eldest sister of the three corporations has lately viewed it with longing eyes, and, in fact, has managed very recently to get a slice of it, although she formerly refused even to taste it, and turned up her nose at the very thought of its being brought to her table. Our contemporary, the 'Lancet,' is now trying the part of Paris, and is again offering the golden apple

although he has not yet got it into his own hands; and inasmuch as it is not possible to steal the fruit, and nobody is strong enough to take it by force, a novel plan is recommended, namely, to buy it, or rather to give in exchange for it all the respectability which the College possesses. It must be added, in justice to the College, that it repudiates the offer made to it; but still, it might find better means of publishing its refusal of the disgraceful barter than by communicating its sentiments to the Medical public in an obscure corner of a weekly periodical, among its answers to correspondents. The announcement to which we refer, inconspicuous as it is, is evidently dictated by authority, and it tells us that the Brighton Memorial was sent by the Fellows of the College to the Council "simply for the sake of shelving it, without hurting the feelings of the memorialists." The same authority, acting no doubt under what the French press calls "inspiration," tells its correspondents that "there is not the very smallest chance of the College accepting the proposal of giving *ad eundem* degrees to Licentiates of the Society of Apothecaries."

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

In our article on the College of Surgeons last week, we quoted some remarks from a published report of a speech made by Mr. Arnott at the late dinner held by the Fellows of the College. He was represented to have said that the College, without any assistance from the State, had raised up and maintained a splendid museum and library, the former having been declined by the Government of the day, when offered to them by the representatives of John Hunter. Whether Mr. Arnott's speech was misreported, or whether that gentleman's memory had failed him as to the facts, we know not; but it was incorrect to assert that the College had received no assistance from the State, inasmuch as sums amounting to somewhere about 30,000*l.* have been voted from time to time by Parliament for the purposes of the museum. It is quite correct, however, that the College is not maintained by the State, as the sums first mentioned were granted for specific purposes, such as the purchase of specimens and the erection of the new building. With this exception, however, the College has no support from the Government, and its maintenance is entirely derived, as we stated, from the fees paid by candidates for diplomas. We are inclined to believe, also, that Mr. Arnott was incorrect in stating (supposing that he was not misreported) that the Government declined to purchase John Hunter's collection. It was *William* Hunter's museum which was declined.

THE INDIA MEDICAL SERVICE BILL.

In the debate upon the India Medical Service Bill on Friday last, in the House of Commons, Mr. Hennessy moved the introduction of a clause requiring the assistant-surgeons to pass an examination as the condition of their appointment as Indian Medical officers; but although the honourable member argued the point with great zeal, force, and ability, he was defeated on a division, and the Bill has passed the House. He contended that the present Bill was only a device to cover the misconduct of the Government in reference to their treatment of the Medical officers; for, in respect to rank, pay, and general position, they had been so badly treated, that there was a difficulty in procuring candidates for that part of the service. Sir Charles Wood's remarks in reply were unfair and evasive, and he actually argued in favour of his measure from the very facts which ought to have been adduced against him. He showed, what is quite true, that there was a deficiency of candidates for the Medical service under the system of competitive examinations, but he concealed the fact that this deficiency arose from the shameful breach of faith committed by the military authorities towards the Medical officers of the army. He also stated that all he proposed to do by the Bill was to enable the assistant-surgeons in the Queen's army to volunteer, if they pleased, into the Indian service; and he expressed his high appreciation of the benefits derived from competitive examinations. Colonel North believed that Sir Charles Wood's argument would be a very good one if our own army found no difficulty in obtaining medical officers, but he could not see how the deficiency in the Queen's service would be obviated by the assistant-surgeons in that service volunteering into the Indian army. But the Government was deaf to all arguments; and although the subject in question was a Medical one, the opinions and remonstrances of all kinds emanating from Medical men were entirely ignored, and the Bill was passed through the Commons, an irreparable injury having thus been inflicted upon the principle of competitive medical examinations as passports to admission into the Army Medical Service.

LEGISLATION ON SYPHILITIC DISEASE.

The very unsavoury subject of the control of syphilitic infection has been introduced into a Bill in the House of Commons, entitled the Contagious Diseases Bill, which, at the time of our writing, has passed through its different stages, and now only awaits its fate in the House of Lords. It will be seen that the sphere of operations contemplated by the Bill is limited in its locality to certain seaport and garrison towns and camps, and in its duration to three years, after which time it may be abandoned, or its provisions may be renewed, according to the success or failure of the experiment. The following are the heads of the measure, which obviously aims at the check of syphilitic disease among soldiers and sailors:—

"The Bill, with amendments, has been reported to Parliament, and issued accordingly. The enactment, which is to continue in force for three years, is to have effect at Portsmouth, Plymouth, Woolwich, Chatham, Sheerness, Aldershot, Colchester, Shorncliffe, the Curragh, Cork, and Queenstown, and in the specified limits of parishes, villages, and places included in or contiguous to the towns and stations named. It will be the duty of an Inspector of Hospitals, chosen for the purpose, to supervise a system of Certified Hospitals. The authorities of any hospital, being desirous that such hospital should be certified, if, on examination and report by the Inspector of Hospitals, the hospital appears to the Admiralty and the Secretary of State for War to be useful and efficient for the purposes of the Act, it will be constituted a Certified Hospital, and will be from time to time visited by the Inspector. Power is given to withdraw this certificate, if the authorities think fit to do so, on the report of the Inspector. This system of hos-

pitals will be utilised as follows. Any authorised superintendent or inspector of police, or any duly registered medical practitioner, can lay before the justice of the peace an information; the justice may, if he think fit, issue to the woman named a notice summoning her to appear personally, or by deputy. In event of the person not appearing, or the matter of the information being substantiated on oath or affirmation, the justice may order the woman to be taken to a Certified Hospital for medical examination. The woman may be apprehended for this purpose. The medical authorities of the Certified Hospital will return to the justice, within twenty-four hours, a certificate of the examination made; and on this the justice may, if he think fit, order the authorities of the hospital to detain such woman for medical treatment until discharged by the authorities. In the case of the patient refusing to submit to the examination, or to the medical treatment, or to the rules of the hospital, she may be summarily convicted, and be imprisoned for one or two months."

A QUESTION IN PSYCHOLOGY.

A man has been lately brought before one of the police-magistrates, charged with sending threatening letters to the Prince of Wales, Sir George Grey, Dr. Begley (of Hanwell), and others. The accused person, it appears, had been an inmate of the Hanwell Asylum from July, 1863, till May of the present year. He was admitted on account of his suffering from delusions; and after having been carefully watched, it was considered that the delusions had left him, and he was discharged cured. Dr. Begley, however, lately received a threatening letter from him, and in consequence he was brought before the magistrate, who asked the following question of Dr. Begley:—"May a dangerous delusion exist, leaving the person so affected sufficient soundness of mind to distinguish between right and wrong?" to which Dr. Begley, who has had a long experience in the treatment of the insane, very cautiously replied, "That this was a very much-disputed question, upon which he would rather not express any opinion." Dr. Begley stated, however, that the delusions were such as to make the individual who entertained them dangerous to the persons threatened, and for this reason he (Dr. B.) had put the matter in the hands of the police. A curious feature in the case is that Mr Haswell, a magistrate, and said to be a Commissioner of Lunacy, could not detect any "delusions" during a conversation with the accused, who had called upon him and conversed with him about his future prospects and intentions. If Dr. Begley alone had been threatened, it is very possible that the affair might have been treated with ridicule, or that gentleman might have been left to the mercies of his rather unwelcome correspondent; but as the Heir Apparent to the Throne and the Secretary of State for the Home Department have also been menaced, it is probable that the case may assume a rather more serious aspect. As the laugh has been against the doctors for some time, it is not unlikely that things may take a turn, and that the public will, in common parlance, have to laugh "on the wrong side of the mouth" in relation to the subject of "delusions."

DAMAGES FOR CANCER CAUSED BY A RAILWAY COLLISION.—At the late Durham Assizes, Mr. Hudson, an ironmaster of Sunderland, brought an action against the North Eastern Railway Company to recover compensation for a cancer in the breast of his wife, caused by a blow received in a collision on that railway in September last. The jury returned a verdict for the plaintiff—Damages 400*l*.

GENERAL CORRESPONDENCE.

MERCURY IN SYPHILIS.

To the Editor of the Medical Circular.

SIR,—On 27th April last, you did me the honour of inserting in your Journal a letter in which I endeavoured to show that the simple treatment, so-called, of Fricke, is absolutely and in fact mercurial treatment, seeing that that gentleman uses corrosive sublimate baths in preference to all others.

In MED. CIRC., 25th May last, Dr. Drysdale demurs to my conclusion in this way:—"Dr. Sisson must surely recognise the distinction between the mere topical application of lotions or baths of nitric acid, sulphate of zinc, or corrosive sublimate, which act as topical irritants and astringents, and the constitutional effects of the drug, when rubbed in, inhaled, or swallowed."

Now, Sir, I beg to state that I do not recognise such distinction, simply because no such distinction exists; and I prove the fact by the following extracts from Taylor "On Poisons"—head, Corrosive Sublimate.

"The readiness with which this poison acts through the skin is proved by the following circumstance:—

"M. Cloquet plunged his hands into a concentrated solution of corrosive sublimate, in order to remove some anatomical preparations. He did not wash his hands afterwards; and in about eight hours he was attacked with severe pain in the abdomen, constriction in the chest, painful respiration, thirst, nausea, and ineffectual attempts at vomiting. Under the use of diluents these symptoms were removed, but for eight days he suffered from pain in the epigastrium."

Again, "Dr. Guerard has seen ptyalism produced as a result of three corrosive sublimate baths (ʒj. of the poison to about ten gallons of water), taken at intervals of three days."

After this I think Dr. Drysdale must cease to quote Fricke as a non-mercurialist. I am, &c.,

R. S. SISSON, M.D.

Maida Vale, 16th July, 1864.

THE BRIGHTON APOTHECARIES AND THE COLLEGE OF PHYSICIANS.

To the Editor of the Medical Circular.

SIR,—The medical practitioners at Brighton, who have made themselves so supremely ridiculous and contemptible by their attempt to obtain the licence of the College of Physicians on condition of giving up their certificates from the Society of Apothecaries, ought to be held up by name to the Profession at large, which I believe has not been the case with the 'Lancet.'

These worthies ought to be aware that all the improvements which have taken place in medical affairs in the last fifty years have either originated or been instigated by the Apothecaries' Society, and that the Profession and the public are more indebted to that Society than to any other medical or surgical corporation.

It has been the fashion of late to endeavour to run down and ignore the Society of Apothecaries; and it appears to be the ambition to catch at every paltry mode of adding "M.D." to the title of the young members of the Profession. The public have, however, become enlightened on the subject, and attach no more importance to the letters M.D. than if they signified "Muddling Dunce."

Pray enable us to suppress the vanity which is tending to ruin the respectability of the Profession.

Your old subscriber, D. G. H.

July 20th, 1864.

[The Licence of the College of Physicians confers no right to the title of M.D.—ED. MEDICAL CIRCULAR.]

GRIFFIN TESTIMONIAL FUND.

To the Editor of the Medical Circular.

SIR,—Acting on behalf of the gentlemen whose names are subjoined, I have had much pleasure in forwarding Dr. Fowler a cheque for 13*l*. 13s., as a contribution to the above fund.

Resident as we are in Weymouth and its vicinity, and therefore the better able to appreciate, not only the incalculable amount of labour entailed upon our *confrère*, Mr. Griffin, by the collecting of facts and working of figures in support of the cause of Poor-law Medical Reform, but also the pure, unselfish motives which have inspired him throughout the arduous struggle in which he has so long been engaged, we gladly avail ourselves of this opportunity to unite with the Profession in paying him a well-merited tribute of respect for the ability, energy, and zeal with which he has invariably advocated this important question. And though it is to be regretted that his efforts have not as yet met with the success they have so eminently deserved, still it must be admitted that the concessions recommended in the Report of the Select Committee are mainly due to the persevering advocacy of our indefatigable townsman.

Impressed by these feelings, and convinced that Mr. Griffin, by his disinterested self-sacrificing labours, extended over a period of nearly ten years, has done honour to our calling, we trust that not only the Poor-law Medical officers, but our brethren generally, will display such *esprit de corps* on this occasion as to demonstrate that, as a Profession, we are capable of appreciating such noble herculean efforts made on behalf of suffering humanity.

In the name of the following contributors to the fund, I beg to subscribe myself Yours obediently,

Weymouth, July 18, 1864. J. MOORHEAD, M.D.

July 20, 1864.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 4TH, 1864.

DR. OLDHAM, PRESIDENT.

The following gentlemen were elected Fellows of the Society :—Mr. E. Des Forges (South Cave, Yorkshire), Mr. Hartley, Dr. G. Hasenfeld (Pesth, Hungary), and Dr. Wharton P. Hood (Lower Seymour street).

Dr. BARNES exhibited a small fibroid tumour of the uterus spontaneously expelled from a patient who had suffered from metrorrhagia.

Dr. GREENHALGH communicated the result of the case of amputation of the cervix uteri mentioned at the last meeting. The patient died some days after the operation, of peritonitis.

Dr. BARNES, remarking on this case, observed that Dr. Marion Sims' method of removing the cervix uteri was superior to the operation by the écraseur, the surface left denuded being smaller, and the risk of peritonitis probably less.

Dr. FUSSELL, of Brighton, exhibited a specimen, consisting of the uterus of a patient who had died five days after removal of a cancerous tumour from the cervix uteri. The interior of the uterus was found diseased, and there were also fibroid tumours in the uterine parietes.

Dr. ROUTH stated, in the course of a discussion which arose on the merits of different écraseurs, that he had found by experiment that the wire-rope écraseur cut through the tissue of the cow's uterus more readily than the chain écraseur.

Dr. GRAILY HEWITT exhibited an entire ovum of seven months' development which had been forwarded to him by Dr. Whitmarsh, of Hounslow. The ovum had been expelled ten days after symptoms of labour had set in.

DR. J. M. GRANVILLE read a paper

ON THE APPLICATION OF EXTREME COLD AS AN ANODYNE IN THE PAIN ATTENDANT ON PARTURITION.

An examination of the phenomena of labour, more especially in relation to the nature, duration, and intensity of the pain accompanying it, has led the author to the following conclusions :—1st. The actual pain (as distinguished from the sensation of forcing) experienced by the parturient woman bears no definite proportion to the force and efficiency of what (for want of a better name) we term "the pains" of her labour. 2nd. The sensation of pain is not invariably synchronous with the occurrence of uterine contraction, the effects of the latter being perceptible to the accoucheur not unfrequently, during examination, before his patient experiences the former.

From these circumstances, taken in connexion with others well known to careful observers, it may be inferred, that the pain attendant on labour is more directly related to the effects of uterine contraction (perhaps mechanical force operating on nervous tissue) than to the specific muscular act itself.

The reference of the pain to some region more or less remote from the contracting uterus or the dilating external passages (in which the seat of pain might have been supposed to be located) appears to support the last inference ; whilst it clearly points to the conclusion, that the pain attendant on labour is neuralgic in its character.

Acting on this theory, the author has tried the effect of extreme cold as a topical anodyne, and the result has been so constant that, after repeated experiment, he feels confidence in bringing this new method of seeking to alleviate the pains of labour before the Society, and suggesting its adoption by the Profession. The method is applicable in all cases, independent of the condition of the patient,—cold being already in use as a powerful means of exciting the uterus to contraction in cases of extreme exhaustion. It is perfectly free from the dangers so inseparable from the most cautious use of anæsthetics. It is perfectly manageable, and may be safely confided to a nurse ; and its *rationale* is in strict conformity with the well-known principles of physiology. It is not intended to remove, but to alleviate, the pain attendant on parturition. It will be found that the power of the uterine efforts is generally increased, without any corresponding increase in the attendant suffering, the patient being not unfrequently under the impression that the pain has ceased when the presentation continues to evidence the continuance of the expulsive force. This has been very remarkable in some of the cases —the pains appearing to be shortened, when examination has proved them to be prolonged. The actual pain is sensibly diminished, the patients expressing themselves variously, but to the general effect that they are relieved of half their suffering.

The method of the application is of the greatest importance. The cold must be extreme, or it is of little if any service, and it must be persistent.

An apparatus was exhibited consisting of a flat tin box, which is filled with a freezing mixture and applied to the seat of the pain.

Dr. OLDHAM believed some difficulty would be found in determining what was the seat of pain. Madame Boivin referred the pain during her own labours to the neck of the uterus.

DR. ALFRED MEADOWS, M.D., read a paper

ON A NEW MODE OF TREATING CASES OF VESICO-VAGINAL FISTULA.

It was contended in this paper, that the usual practice of keeping the patient in bed for two or three weeks after the operation for the cure of vesico-vaginal fistula is unnecessary, and that, on the contrary, she may be allowed with perfect safety to go about as usual immediately after the operation. The author showed that the reason given for the former practice—viz., that the parts should be kept quiet, is as fully attended to in the plan suggested as in that usually followed, because the movements of the body do not interfere with the quietude of that particular portion of the floor of the bladder where the fistula existed, there being no muscles in this region which can by their attachments prejudicially affect the part in question. With regard to the second consideration,—that the urine should be kept from the surface of the fistula, either by the constant employment of the catheter or by its frequent use,—the author exposed the fallacy of this argument by briefly reviewing the circumstances which exist after every operation of this kind. At first the bladder is quite empty, but, as urine gradually flows into it, the organ becomes slowly distended; and the very fact of this distension taking place by the uniform pressure of the urine, proves that contact of that fluid with every part of the bladder-wall cannot be avoided; no position of the patient can prevent it, and consequently the recumbent posture is not needed on this account, nor is the use of the catheter of any service. Two cases were detailed in which the plan here suggested by the author had been carried out with perfect success. In one, where chloroform was not administered, the patient went about immediately after the operation, and followed her usual avocations. In the other case the patient had chloroform and on this account chiefly she kept in bed that day; but the next day she was allowed to go out, and her cure was equally complete. In both cases the opening was large enough to admit the finger easily; and in one of them it was situate far in the vagina. The author recommended the use of many sutures, merely twisting them, and without either clamp or shot; he also advised that they should be allowed to remain some time to secure firm union, their presence occasioning no inconvenience. One of the cases cited was further remarkable inasmuch as by the process of sloughing which had previously taken place no trace of the uterus could anywhere be discovered, and the patient has continued, for some time past, to menstruate through the bladder.

Dr. OLDHAM thought it a great point to save patients from the irksomeness of wearing apparatus; and by showthat the confinement hitherto considered necessary was not required Dr. Meadows had done good service.

Dr. A. HARRIS related a

CASE OF HYDRO-ENCEPHALOCELE.

The subject of this case was the thirteenth child. A tumour hung from the back of the head at the upper part of the occipital bone; it measured nine inches round, and was four inches and a half long; it contained fluid. The day after birth, four ounces and a half of a highly albuminous fluid were removed by a canula and trocar. Two days later it was again punctured. Nine days later a spontaneous evacuation occurred. The child wasted gradually, and died when three months old.

Mr. NUNN related a case of

DESTRUCTIVE INFLAMMATION OF THE HIP-JOINT IN A PUERPERAL WOMAN.

The patient was admitted into the Middlesex Hospital twenty-seven days after delivery of her second child, complaining of pain, swelling, &c., of the right hip. She had a patchy tongue, glazed fauces, and a pulse of 130. No inflammatory or other disease of the pelvic viscera. According to the patient's account, she suffered some post-partum hæmorrhage, and for three weeks had offensive discharges. The pain in the hip commenced nine days after delivery. The infant was suckled no longer than fourteen days. On the thirty-sixth day Mr. Nunn passed in deeply a narrow bistoury at the back of the trochanter, and gave exit to twelve ounces of pus. On the forty-fourth day rigors came on, and on the forty-eighth day death took place. The post-mortem examination revealed most extensive denudation of the head of the femur, the cotyloid cavity, and neighbouring osseous structures; no invasion of the pelvis by matter through the thyroid foramen; the uterus and other pelvic viscera not visibly affected; in the lower lobe of the left lung a small solidified patch the size of a bean, with a yellowish softened centre. Joint disease the author believed was generally accepted to be one of the consequences of puerperal fever, and under such circumstance to be the result of pyæmia. The question was—Is there a liability to joint inflammation peculiar to the puerperal state independent of ordinary purulent infection characterised by an absence of acute constitutional symptoms? The author related a case by Dr. Fenwick bearing on this point. He expressed a conviction that many analogous cases lay scattered over, and so to speak fossilized in, the experience of accoucheurs; and that it would be well, if his conviction should be justified by facts, that something more definite than is to be at present found in surgical text-books were made available to the student by these cases being brought to light. The obvious practical point was regarding the moment when an incision into the joint might justifiably be made, so as to relieve the system of the grave complication of pent-up matter.

Dr. MARTYN gave the particulars of an interesting case somewhat similar to Mr. Nunn's; the patient recovered, however, after an illness of many months' duration. The abscess should not, he believed, be opened. Rest was very important.

Mr. NUNN, in reply, said that it was curious to observe, in consulting various works, that the surgeons had apparently left the question of puerperal joint disease to the obstetricians, and that the obstetricians had tacitly relinquished it to the surgeons. A very important and highly interesting matter had thus, between the two, not received that elaboration which it required.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 28.

Mr. PARTRIDGE, President.

Dr. SAMUEL FENWICK read a paper

ON THE CONDITION OF THE STOMACH AND INTESTINES IN SCARLATINA.

The object of this paper is to prove the following propositions:—1st. That the mucous membrane of the œsophagus, stomach, and intestines, is inflamed in scarlatina. 2nd. That desquamation of the epithelium of these parts takes place. 3rd. That, notwithstanding the anatomical changes in the mucous membrane of the stomach, the formation of pepsine is not prevented. 4th. That the condition of the skin is similar to the condition of the mucous membrane in scarlatina. In support of the first proposition, the microscopic examinations of the mucous membranes of the œsophagus, stomach, and intestines were detailed in ten cases of death from scarlatina during the first week of illness, and in six cases who died in the second and third week of the fever. The first effects of the scarlatina poison upon the mucous membrane of the stomach were shown to be the congestion of the blood-vessels and the stripping the epithelium from the tubes and the surface of the organ, and also the softening of the tissues. The tubes are greatly distended by granular and fatty matters, or by small cells intermixed with granules, and in some cases they are lined

by a newly-formed membrane. Sometimes no normal cells can be distinguished ; in other cases they are present, but are scattered irregularly. After the second or third week the tubes are found less distended than at an earlier period, and whilst their closed ends are still loaded with granular matters, which greatly obscure the gastric cells. These become more evident towards the surface of the mucous membrane. The cells at this period are sometimes very large, sometimes loaded with fat or coated with granules, and seem to have but little adhesion to their basement membrane, as they readily separate from the tubes, but adhere closely to each other. The effects of the inflammation upon the intestines seem, in slighter cases, to consist in the effusion of granular and fatty matters into the mucous membrane ; but in more severe cases the tubes of Lieberkühn are obstructed by epithelial cells, whilst extravasations of blood take place in the villi, and these, with the rest of the mucous membrane, are loaded with small cells and granules. In one case the mucous membrane was entirely stripped of villi, excepting a few fragments which still remained, and the enlarged and prominent openings of the follicles of Lieberkühn gave its surface the appearance of a sieve. In some instances in which the pancreas has been examined, evidences of disease presented themselves. The second proposition was stated to be more difficult of proof, inasmuch as vomiting usually occurs only in the first stage, and the author had no opportunity of examining the vomited matters at this period of the disease. In one case, in which vomiting took place in the third week, fibrinous casts of the stomach tubes were discovered, and inflammation of the mucous membrane was proved to have existed by post-mortem examination. The chief reason upon which the opinion that desquamation of the epithelium occurs was founded, was from the microscopic examination of the contents of the stomachs of those who had died of this disease. The contents in recent cases consisted of pieces of fine membrane, of cells, and of granules and shreds of membrane. The membranes were of the shape and size of the tubes of the stomach, and were covered with granules and fat. The cells varied from 1-1200th to 1-2200th of an inch, and were usually fringed with fine pieces of membrane. In cases of longer duration the membranes were covered with cells, and were also of the size and shape of the stomach tubes. In order to ascertain if these appearances were trustworthy as evidences of inflammation, the contents of the stomachs of forty-five subjects were examined at the Middlesex Hospital, the condition of the mucous membrane being at the same time noted. In only one were there any fibrinous casts, and it was in a case of acute gastritis. In eighteen there were only separate cells, chiefly of the columnar form, and in none of these was there any inflammatory action. In eight cases casts of the upper parts of the tubes were plentiful, composed only of healthy conical cells, and in all the mucous membrane was in a natural condition. In eighteen there were either plugs formed of cells and granules from the secreting parts of the tubes, or the casts of conical cells were overlaid with granular matters, and in all of these the stomach was more or less inflamed. Two cases of gastritis, unconnected with scarlatina, were also quoted as examples of the forms in which casts of the stomach tubes appeared in vomited matters during life, and the author stated he had detected casts of the stomach tubes in matters vomited by persons affected with gastritis connected with diseased kidneys, with inflammatory dyspepsia, and other forms of inflammation of the gastric mucous membrane. It was urged that if casts of the gastric tubes can be discovered during life in cases of gastritis, and if in scarlatina this condition exists, and casts have been found in the stomach after death, there is every probability that desquamation of the epithelium takes place in this organ as it does in the skin and the kidneys. In support of the third proposition, the results of the following experiments were given in three cases of scarlatina :— Ten grains of hard-boiled white of egg were digested at a temperature of 90° for twelve hours in an infusion of the mucous membrane, to which 3 per cent. of hydrochloric acid had been previously added. The average loss of albumen was three grains and two-thirds. Similar experiments performed with the stomachs of eleven males, who died of various diseases at the same hospital gave an average loss of four grains ; so that there had been scarcely any diminution of pepsine produced by the fever. As a contrast to this were the results of similar experiments upon four cases who died of typhus fever. In two of these the albumen had gained three grains of weight by imbibition, and was not at all softened ; whilst in the other two it was softened, and one had lost only half a grain, the other one grain and a half in weight. But as the activity of the digestion must depend, not only upon the relative amount of pepsine, but also upon the bulk of the mucous membrane, this was also attempted to be estimated. The average weight of the mucous membrane of the stomachs of ten males dying of various diseases at the Middlesex Hospital was eighteen drachms, the weight of two recent cases of scarlatina was eighteen and sixteen drachms (the latter being in a boy), whilst it only amounted to fifteen drachms in one who died in the third week of illness. In four cases of typhoid fever the average weight of the mucous membrane only reached eleven drachms. Under the fourth proposition it was stated that the skin had only been examined microscopically in three cases. In the first in which the patient died after a few days' illness, the only morbid appearances in the cutis was an occasional minute extraarsation of blood in the neighbourhood of the sudoriferous ducts. The rete mucosum was greatly thickened, and numerous round cells with large nuclei were everywhere visible, intermixed with the natural cells. The basement membranes of the sweat-glands were thickened, and the epithelium lining them was so much increased that in most cases it obstructed their channels. In some of the sweat-glands the coils of which they were composed were loaded with coagulated blood, and were greatly and irregularly distended. In the other recent case the appearances were similar, excepting that the external layers of the cuticle were stained with blood in minute patches, and the sweat-ducts were also reddened ; but there were no extravasations of blood either in the glands or cutis. In some of the ducts the epithelium was detached from the basement membranes. In the case of a man who died during the third week the sudoriferous tubes were still choked up, but in the glands the epithelium seemed in many places to be torn away, leaving the basement membranes bare, or only covered by ragged particles. The cutis was in a natural condition. The author stated that although he had, in accordance with the usual custom, described the appearances of the skin and mucous membranes as the results of inflammation, yet that certain considerations suggested the idea that the term when so used was perhaps misapplied. In scarlatina, we find that in each part the morbid condition is mostly confined, in the first instance, to the basement membranes, and consists in the formation of layers of new cells, which, in the skin, are transformed into cuticle of natural appearance, and in the stomach contain pepsine. If future researches should prove that a similar condition occurs in the kidneys and other parts, it will be necessary to look upon the structural changes produced as resulting from increased physiological, rather than from pathological action ; and that the primary effect of the scarlatina poison is suddenly and violently to stimulate the natural cell-growth of the various secreting organs.

Dr. WILSON FOX said that he had listened with much pleasure to Dr. Fenwick's very able paper. It had possessed an especial interest for him, inasmuch as Dr. Fenwick's observations on scarlatina confirmed those which he had himself communicated to the Society in 1858, on the condition of the stomach in a variety of acute diseases, including variola, typhoid and puerperal fevers, pneumonia, peri- and endocarditis, cholera, and many others, in which he had found the stomach in a condition very closely resembling that described by Dr. Fenwick, and which, after Professor Virchow, he had designated as one of acute catarrh, the mucous membrane being hyperæmic, swollen, and cloudy-looking, and covered with very tenacious mucus. This condition Dr. Fox had always found associated with a granular condition of the epithelial cells, which were shed

with great facility both from the surface of the membrane and from the interior of the tubes, and were found in great numbers, and often enlarged and presenting multiple nuclei in the tough mucus covering the surface. Dr. Fox said that since he had made these observations he had been in the habit of regarding the furred condition of the tongue in acute diseases as an index of the same irritative production of epithelium through the gastric intestinal tract. He had also at the same time been able to point out, on anatomical grounds, that chronic affections of the stomach were frequently associated with chronic affections of other organs. On some points of detail Dr. Fox said that his observations differed from those of Dr. Fenwick. He had not examined with the microscope stomachs of patients dying from scarlatina, but the appearances which these presented to the naked eye corresponded so closely with those to which he had alluded that he spoke on them with more confidence than he should otherwise feel inclined to do. He still thought, as he had pointed out in his original paper, that the granular matter which Dr. Fenwick described as occurring free in the tubes was really contained in the interior of epithelial cells, and that it was only in the severest cases of acute gastritis, in which the cells became at once broken down, that the granular matter was found free. With regard to the casts of tubes described by Dr. Fenwick, Mr. Fox, not having examined the stomachs of scarlatina patients, could not make any positive observations, but he had never found any in the cases of other diseases which he had mentioned. He had, however, often observed appearances in the mucus having a most deceptive resemblance to casts, from the manner in which the epithelial cells were agglutinated by the tough mucus. He did not think that these casts, if they did occur in the stomach, could be of a fibrinous nature any more than the first epithelial desquamations from the kidney in the early stages of Bright's disease possessed that character; nor was he of opinion that the membrana limitans of the gland separated with the epithelium. He believed that when the membrana limitans (when it existed) was destroyed or injured, the power of reproducing epithelium was impaired or lost. Epithelium often separated in continuous masses from mucus surfaces and from the interior of glands.* Such desquamation was not only exceedingly common under conditions of irritation, but was also under some circumstances a physiological act. It had been noted long ago by Mr. Goodsir during digestion, and many recent observations on this subject were contained in Virchow's Archiv. Dr. Fox was of opinion that Dr. Fenwick's observation, though very valuable as evidencing the participation of the stomach and intestines in the consequences of the scarlatina poison, did not show anything specific in that organ, or peculiar to the disease in question.

Dr. WEBSTER had listened with great gratification to the paper, especially as it confirmed what he had observed as to the employment of remedies in scarlet fever. It gave a great additional value to the minute researches of the author that they had a practical bearing in treatment. Dr. Webster then related instances in which the internal administration of irritating remedies, especially purgatives, did harm. He referred also to the bad effect of articles of diet which were sometimes given to children in scarlet fever to tempt the appetite; and, lastly, alluded to the good effects of sponging the skin with tepid water and vinegar.

Dr. MURCHISON said that he had examined the stomach in twenty cases of scarlet fever, and found, on the whole, similar appearances to those described by the author, but he agreed with Dr. Fox that the granules were in the interior of the epithelial cells. He had not seen any casts. He thought, however, that the author had called attention to an important complication, but he (Dr. Murchison) could not agree that it was of universal occurrence, as he had examined the stomach in several cases of scarlet fever and had found it quite healthy; and, on the other hand, he had found changes like those in scarlet fever in the stomachs of those who had died of other diseases.

The AUTHOR said the question was one of experience, and continued examination would no doubt settle the question. In every case that he had examined during four years, he had found the changes he had described. In some cases of scarlet fever the skin was not affected, and yet it was still called scarlet fever, and just so in a few the stomach might escape. Still we should in a large number find evidence of inflammation of the stomach. The paper was chiefly to draw attention to the subject. In reply to Dr. Fox, he said that he had made the sections straight with a double-bladed knife, and examined them by a low power with a parabolic condenser. He had found casts, best in children who had died a few days after the disease began, but in other cases he had not found them, and sometimes he had only found plugs as described by Dr. Fox. These plugs, he had no doubt, were the result of inflammatory action. After a few further remarks the speaker was obliged to conclude abruptly, as the time for reading the remaining papers was very limited, this being the last meeting of the Society.

(To be continued.)

* Dr. Fox begs us to append to his remarks a fact which he omitted to mention to the Society, that he has notes of a case of acute inflammatory diarrhœa, which came under his observation some years ago, and of which he has preserved drawings of casts of the crypts of Lieberkühn, found in the intestinal mucus.

OBITUARY.

JAMES BIRD, M.D., F.R.C.P., F.R.C.S.

We regret to have to record the decease of Dr. James Bird, late Physician-General to the Bombay Army, and Lecturer on Military Surgery and Tropical Medicine and Hygiene at St. Mary's Hospital. His death took place on the 10th inst., at the age of sixty-seven. Dr. Bird had long retired from the service, but his mind was by far too active and his zeal too great to allow him to spend in idleness the time of retirement. He was a man of great energy and fine *physique*, and took the warmest interest in all that concerned State medicine and the health of armies. In 1862 he was Lettsomian Lecturer on Public and Private Hygiene at the Medical Society of London, of which he was also vice-president and treasurer, taking an active interest in its affairs. Dr. James Bird was a great authority on military medicine and surgery and military hygiene, and we published in the 'Lancet' of 1855 some important lectures from him on these subjects. He was foreign secretary for India of the Epidemiological Society, and a zealous supporter of that useful body. Dr. Bird was much esteemed as an adviser by the medical and military authorities of the army, and his advice was often taken on matters of imperial importance. His contributions to current literature on his favourite subjects of military medicine and general hygiene were numerous and valuable. He leaves many friends, who admired his character and respected his powers of mind.—'Lancet.'

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on the 20th inst, the following gentlemen, previously Members of the College, were admitted Fellows of the same:—George Harley, M.D., Harley street; James Edward Pollock, M.D., Upper Brook street; William Overend Priestley, M.D., Hertford street, Mayfair; William Wood, M.D., Upper Harley street.

At the same meeting, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—Leo Charles Da Silva, Burntwood, Wandsworth; John Lewis Jones, Carnarvon; John Wickliffe Jones, Assist.-Surg. R.N.; William Skinner, Sheffield; Thomas Haywood Smith, Alcester.

The following gentlemen were reported by the Examiners to have passed the first part of the professional examina-

tion for the Licence:—Francis Bateman, St. Bartholomew's; Stephen W. Bushell, Guy's; Henry Clothier, University College; Thomas Cole, St. Bartholomew's; Henry Cribb, Bishops Stortford; Henry Denne, Guy's; William S. Eccles, St. Bartholomew's; John S. Ferris, King's College; John Gill, Guy's; George W. Malin, Sydenham College, Birmingham; Robert Robinson, St. Bartholomew's; George A. Rogers, Commercial place, Commercial road; Henry Rundle, St. Bartholomew's; Reginald P. Simpson, Gower street; Francis M. B. Sims, Sackville street; Wm. Skinner, Ampton place, Gray's inn road; William A. P. Stuart, University College; John Stuckey, University College; Theodore T. Taylor, St. Mary's; John B. Welch, King's College; James A. White, Salford; Edward F. Willoughby, University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 19th inst., and when eligible will be admitted to the pass-examination:—W. A. Creaser, Hull; W. B. Dawson, London Hospital; G. N. Dunn, Dublin; J. M. Gibbes, St. George's Hospital; Richard Jeffreys, Sheffield; James Kelly, Dublin; Thomas Laffan, Dublin; R. R. S. C. C. Lloyd, Guy's Hospital; F. W. Lowndes, Edinburgh; W. G. Martin, Manchester; W. J. Mountain, Leeds; Alderson Newsam, Guy's Hospital; W. H. Pywell, Guy's Hospital; J. H. Quinn, Dublin; J. D. Rowlands, Guy's Hospital; W. B. Swann, Leeds; T. A. Turner, Charing cross Hospital; James Wickham, Middlesex Hospital.

The following gentlemen also passed their primary examinations on the 20th inst.:—J. W. D. Bain, Westminster Hospital; Merry Clarke, Edinburgh; Petros Constantinides, Canada West; J. E. Coxwell, University College; Francis Derbyshire, Manchester; J. S. V. Fifield, King's College; J. M. Fraser, Canada West; Eustace Greenaway, London Hospital; F. R. Haward, St. Bartholomew's; S. S. M'Millan, University College; W. J. Marsh, Guy's; Campbell Orme, St. Bartholomew's; T. H. Redwood, St. Bartholomew's; William Roberts, Manchester; S. H. Smith, King's College; R. B. Wall, St. Mary's; J. M. Whitwell, University College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 14th inst.:—John Frederick Foster, Old Court, Guernsey; Henry William Freeman, Bideford, Devon; Henry Hope, St. Bartholomew's; Albert Comberbach Reade, St. Bartholomew's; Duncan Francis Sinclair, Halstead, Essex.

As an Assistant:—Walter Alfred Marsh, New Kent road.

PRESENTATION.—On Thursday evening, the committee of the Cottage Hospital presented Dr. Wyllie with a testimonial, in recognition of his gratuitous services in connection with the hospital during the first six months of its existence. In the absence of the mayor, the presentation was made by Mr. Crapper, who, in very eulogistic terms, referred to the very valuable services rendered by Dr. Wyllie, and the success which had attended his operations, and which was a proof of the doctor's skill and ability. Several other members of the committee spoke in complimentary terms of the manner in which the doctor had managed the surgical department of the hospital. The Doctor, in feeling and appropriate terms, acknowledged the gift, which, he assured them, he would ever cherish with feelings of gratitude, and which would serve as a stimulus to renewed efforts in rendering the hospital as useful as possible. He felt it his duty to acknowledge the assistance he had received from the other medical men in the town, to whom he was much indebted for the readiness with which they had aided him on all occasions. He advised the committee to set about raising a building fund, as the erection of an hospital would not only secure the sympathy and support of the public, but would materially facilitate the efforts of the surgeons and the recovery of the patients. The testimonial, which was raised by voluntary contributions among the members of the committee, consisted of a number of very valuable medical works.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, JULY 27.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, Caledonian road, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, JULY 28.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, JULY 29.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, JULY 30.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

MONDAY, AUGUST 1.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, AUGUST 2.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Expeditious Writing: Two New Systems. Stenography. By W. Hall, F.R.C.S. London: J. Stevenson, Paternoster row, E.C.

Prize Poems.

The Treatment of Consumption. By M. Corner, M.D. London: R. Hardwicke, 192 Piccadilly.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

DR. J. MOORHEAD, *Weymouth.*—The communication is inserted.

DR. ROBERT FOWLER.—The list has been received.

D. G. H.—The letter is inserted.

DR. R. SISSON'S letter is published.

From Lower Norwood.—5s. worth of postage-stamps have been received for the distressed family of the late Mr. Edgar Bull, and 2s. 6d. worth for the Griffin Testimonial. These stamps have been sent to the recipients of the respective funds.

MR. J. Z. LAURENCE'S paper will appear next week.

THE Return of Births and Deaths in the City of Dublin has been received.

To the Editor of the Medical Circular.

SIR,—Professional men and others are cautioned against a limping farmer-like man, dressed in a black coat, drab vest and trousers, charged with purloining from my consulting-room a stout silver-mounted cane, knotted one inch apart; much valued because of its being a present. Notice has been given at the Police-office, Scotland yard.

I am, &c., J. K.

July 17, 1864.

DR. B.—We understand that the *Cocculus Indicus* was introduced into the British Pharmacopœia by the influence of a distinguished Scotch Professor, the drug having been previously admitted into the Edinburgh Pharmacopœia.

INQUIRER.—The institution in question is not supported by the money received for diplomas, but the examiners are paid in proportion to the number of candidates who are passed; which we have already denounced as a most unwise arrangement.

MR. R. B.—We have not yet received the information which we anticipated in reference to the probable success of the plan proposed. Without such information we are unable to move in the matter.

A POOR-LAW GUARDIAN.—The licence in question does not confer any right to assume the title of Doctor. It is received by the Poor-law Board as equivalent to a single qualification.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON THE SYMPTOMS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

By Robert Hunter Semple, M.D.,

Member of the Royal College of Physicians of London, Senior Physician to the St. Pancras and Northern Dispensary, Physician to the Standard Life Assurance Company.

(Continued from page 17.)

Disease of the Right Side of the Heart.—It may be stated in general terms, that valvular disease of the heart is far more common on the left side than on the right; and, therefore, when there is any peculiar difficulty in the diagnosis, the chances are that the left side is affected. The reason why the left side is the most liable to disease may be easily explained by reference to the greater amount of work performed by the left ventricle in comparison with the right, the first propelling the blood to the whole system, and the second sending it only to the lungs. Nevertheless, the right side of the heart *is* sometimes affected; and, although the diagnosis by auscultation is difficult, yet there are collateral circumstances connected with the pulse and the venous circulation, in addition to the stethoscopic signs, which tend to throw light upon the real nature of the case.

When the mitral valves are affected, the murmur is heard over the apex of the heart, and on the left of the sternum; but although the tricuspid valves may be diseased, so as to permit regurgitation (which is not infrequent) this circumstance may be unaccompanied by any morbid sound, or at any rate it may escape detection. No positive rule can, therefore, be laid down for the diagnosis of tricuspid from mitral regurgitation; but when a murmur is heard both at the left side of the apex of the heart, and also at the epigastric region, it may be assumed that both the auriculo-ventricular valves are diseased. When the aortic valves are diseased, there is, as has before been noticed, a murmur over the base of the heart, either single, indicating obstruction, or double, indicating obstruction with insufficiency of those valves; but when the semilunar pulmonary valves are affected (which is not common) the murmur will be propagated along the third costal cartilage of the left side. It is right to mention that Dr. W. T. Gairdner considers that tricuspid regurgitant murmurs are not rare; their seat, when they are heard, is immediately over the ensiform cartilage.

But the examination of the veins of the neck affords valuable information in disease of the valves on the right side of the heart. As the right receives the blood from all parts of the body through the venæ cavæ, it is evident that when the tricuspid valves are obstructed or insufficient the blood will be thrown back upon, and accumulate in the veins which supply the venæ cavæ; and hence, the latter will become turgid and congested. The veins coming from the upper extremities and the trunk cannot of course be seen, but those in the neck are visible; and accordingly it is found that the jugular veins are either simply swollen, or become the seat of actual pulsation, when any cause exists which retards the course of the blood in the right cavities, and especially in contraction or insufficiency of the tricuspid valves.

It may be repeated, however, that the left side of the heart is very much more frequently diseased than the right. The most common murmur is that which is heard synchronously with the contraction of the ventricles, and if it is heard simultaneously over the base and the apex of the heart, it indicates both obstructive disease of the aortic valves, and insufficiency of the mitral valves; and this is a very common, and, indeed, the most common, complication. When a double murmur is heard over the base of the heart, it indicates the existence of obstruction to the passage of the blood, together with regurgitation through the aortic valves; but a diastolic murmur over the apex of the heart is a rare occurrence, even although the conditions for producing it may be present—namely, obstructions of the mitral valves.

(To be continued.)

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.,

Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 34.)

The Causes, Diagnosis, and Treatment.

Partial Separation of the Placenta morbidly Adherent.—I shall not enter into the pathology of morbid adhesion of the placenta, as in our present state of knowledge it is not of any practical importance so far as the treatment is concerned. If we were able during pregnancy to ascertain the existence of disease of the placenta, we might perhaps, by appropriate treatment, prevent it from going on to morbid adhesion. Abdominal pain and constitutional disturbance are the symptoms which are said to accompany inflammation of the placenta, but they are not pathognomic of that affection, as they are so often present during the latter months of pregnancy from causes quite unconnected with the placenta. Most practitioners must have observed that women not infrequently suffer from pain during gestation in the uterine and lumbar regions with the pulse quickened, and yet after delivery the placenta comes away easily, and appears perfectly healthy. Sometimes, also, disease of the placenta occurs so insidiously, that it does not give rise to any symptoms.

Diagnosis.—The uterus externally is felt large, and alternately *hard* and soft. The patient complains every now and then of "pinching pains" in the lower part of the abdomen. On making an internal examination, the insertion of the cord cannot usually be reached, showing that notwithstanding the contractions of the uterus, the placenta is still attached. If we draw upon the cord firmly, the patient complains of pain, and on letting it go it is felt to recede. During uterine contraction, the interior of the cervix just within the os uteri will be felt hard, like gristle. The amount of hæmorrhage depends chiefly upon the extent of the adhesion. Should the discharge be slight, we may be pretty sure that nearly the entire placenta is adherent. It depends partly also on the amount of uterine contraction. The hæmorrhage is most profuse when there is inertia of the uterus, as well as partial morbid adhesion of the placenta.

Treatment.—It is very similar to that of hæmorrhage arising from partial separation of the healthy placenta. When the hæmorrhage occurs within a few minutes after delivery, we cannot be certain that the placenta is *morbidly* adherent; because in that short time uterine contraction will either not have commenced, or only occurred once or twice. We should therefore, in such cases, first try strong pressure. If, on the other hand, flooding does not come on until several strong contractions of the uterus have taken place without the afterbirth becoming totally detached, the treatment may be commenced by introduction of the hand, and removal of the placenta. This is one instance in which ergot not only does no good, but does harm. It increases the difficulty of the operation, by making the uterus contract firmly upon the placenta, and it tends sometimes to complicate the case by setting up irregular or hour-glass contraction. When the placenta is morbidly adherent, it is not so easy to detach as when it is healthy. The side to side movement of the fingers does not generally answer; it must be effected by flexing and extending the fingers. If possible, the whole of the placenta should be peeled off *in one piece*; because, on its removal, we can tell with a considerable degree of certainty whether we have taken away the whole of it or not. In some rare cases, the placenta

has to be removed in pieces, and then we can never be quite certain that we have not left a piece behind.

Illustrative Cases.

I.—In the following instance there was suspension of the action of the uterus, as well as adherent placenta:—Mrs. B., æt. twenty-one, primipara, had a very lingering labour. A short time after the delivery of the infant, I found the pulse very rapid and weak. On passing my hand under the clothes to make a vaginal examination, I came in contact with a large mass of clots, lying in the bed. The root of the placenta could not be felt. I compressed the uterus with the hand, but no good was derived. The blood poured away so fast, that in a few minutes I could hardly feel the pulse. I ordered the mother of the patient to administer brandy freely, while I removed the placenta with the hand. About two-thirds of it was attached and strongly adherent. Afterwards, the uterus was kept under command by the hand for a time as a precaution, and no further loss occurred. The patient was very feverish for a few days, but ultimately did well. I may state, as worthy of note, that during the labour, the mother of the patient expressed a hope that her daughter would not flood after labour, as she always did after her confinements. She said she had nearly lost her life after each delivery from flooding, and, in each instance, it was only arrested by detaching the placenta with the hand. I know that some practitioners believe in the hereditary predisposition to hæmorrhage; but the above instance looks very like as if there might also be a hereditary tendency to disease of the placenta. It would be interesting to know the subsequent obstetric history of this patient.

II.—Mrs. T., æt. thirty-five, mother of eight children. The placenta was adherent in four of her previous confinements. For the last six months of the present pregnancy, she has felt a constant pain in the right iliac region. She was attended in her labour by one of the students of the Queen's Hospital. He says that the labour was quite natural, and after delivery uterine contractions set in to detach the placenta. Severe hæmorrhage soon commenced. On examination, the insertion of the cord could not be felt. Applied pressure and cold and gave brandy. In half an hour, that gentleman succeeded in arresting the hæmorrhage, and having waited ten minutes more, sent for me, as the placenta had not come away. One of the rules framed for the guidance of the midwifery pupils of the Queen's Hospital was, that if the placenta did not come away in forty minutes, the student was to send for the surgeon-accoucheur of the district. The rule is not now in existence; it was very unsafe. In this case, the student ought to have sent for me before; he waited, however, forty minutes, according to rule. When I arrived, the child had been born one hour and ten minutes. Fortunately, there had not been any flooding for some time, but she was in a great state of prostration from what she had lost. On an internal examination, I could not feel the insertion of the cord. I then introduced my hand and removed the placenta. The greater portion was adherent. Although there was no further hæmorrhage, she was in a very feeble and dangerous state for three days, and her recovery was slow, but complete.

Irregular Contraction. Hour-glass Contraction.—I have alluded to one form of irregular contraction which sets up hæmorrhage by separating a portion of the placenta. In this variety, only a small part of the uterus is contracting, while the rest is in a state of inertia. Besides this simple form of irregular contraction, we have others in which the circular fibres of the uterus are chiefly implicated. The os uteri sometimes contracts rapidly after labour, and prevents the detached placenta from being expelled or withdrawn by traction. When flooding occurs in such cases, it is on account of the presence of the placenta not allowing the uterus to contract to its minimum. In other instances, the circular fibres of the uterus, at any point above the os uteri, and below the fundus, contract so as to divide the cavity into two compartments. The hæmorrhage, in hour-glass contraction, depends very much upon the position of the circular constriction. If the placenta is situated at the fundus, the nearer the contraction is to that spot the less will be the hæmorrhage; and the nearer it is to the os uteri, the more profuse will be the flooding. When the constriction is very high up, it cuts off all the supply of blood from below, and it renders the upper compartment so small, that blood cannot escape, on account of the placenta filling it up, and acting as an efficient plug to the uterine sinuses. When the hour-glass contraction is situated near the os uteri, the blood from the spermatic and uterine arteries flows on to the sinuses unobstructed, into the large upper cavity.

Hour-glass contraction is generally attributed to the effect of ergot, or premature traction of the cord. I believe, in the majority of cases, its primary cause is morbid adhesion of the placenta, and that neither ergot nor traction on the funis will produce it, unless that condition of the placenta also exists. The uterus contracts to detach the placenta, and failing to do so, spasm or cramp of a certain layer of muscular fibres is excited. Ergot and traction of the cord would both stimulate the uterus to contract more forcibly upon the adherent placenta, and in that way would be more likely to induce the spasm.

Diagnosis.—If the hæmorrhage is due to simple retention of the placenta by contraction of the os, it will be ascertained on making an internal examination. The os will be found contracted, the cervix hard, and the insertion of the cord felt through the os. Moderate traction on the cord will fail to draw the placenta through. The uterus externally feels moderately contracted. The diagnosis of hour-glass contraction, until the hand is passed into the uterus, is very unsatisfactory. Some say that the constriction can be felt through the abdominal walls, while others hold the reverse opinion. It does not matter much, because the hæmorrhage is not caused by the hour-glass contraction, but is due to the partial separation of the adherent placenta. The treatment of the case is to get away the placenta. We pass our hands into the uterus with that object, and then we find the additional complication.

Treatment.—When the os is contracted, it must be dilated gently by the fingers, and the uterus emptied of its contents. I have a few times treated these cases by applying strong traction on the cord, at the same time getting the nurse to press on the uterus externally. The os has gradually yielded and allowed the placenta to pass through. I think the first plan is safer, because we cannot be quite sure that a portion of it is not still attached; and also, from the force required in pulling the placenta through, there is danger of breaking off the cord.

In hour-glass contraction, the hand must be insinuated in the same way through the constriction, and the placenta separated by the fingers. No one can have an idea of the difficulty there is in passing the hand through an hour-glass contraction until they have tried it. The more you try to dilate it, the more it seems to contract. The administration of chloroform very much facilitates the operation. If, after steady perseverance for some time, the contraction will not allow the whole hand to pass, the placenta must be picked away in pieces by as many fingers as can be passed through.

ORIGIN AND NATURE OF SYPHILIS.

By Dr. Sisson.

(Continued from page 52.)

Mr. Carmichael says: "The eruption is usually ushered in by considerable fever, pains in the different joints, and frequently with dyspnœa and pain in the chest—symptoms which often demand the repeated use of the lancet."—('Venereal Diseases.')

Swediaur writes: "I remark, that every author who wrote when the venereal disease first appeared has called it pestilence or pestilential disease."—('Syphilitic Diseases,' vol. i.)

Dr. Copland and other writers have described several epidemic outbreaks of syphilis, commencing with that of 1494, which has been always mentioned as such; and when we remember that in less than two years the disorder had

spread over France, Scotland, Germany, and Hungary, we are incapable of designating it by any other name.

We know, moreover, that syphilis will get well under a variety of treatments, and may do so under no treatment at all. Besides, Astruc was in error in supposing that the "epidemics" treated of epidemic diseases alone, and that those to which no treatment was appended got well spontaneously.

Dr. Adams, the learned translator of Hippocrates, says: "The Books of Epidemics can be viewed in no other light than as an adversaria or memorandum-book of isolated facts and detached observations, in which the lineaments of a particular disease are seldom to be recognised, and in which there is a general omission of any mention of treatment."

I wish to throw no contempt on those who were wise in a bygone generation, but if we wish to be considered wise in our own—and it is true, as stated by Dr. Laycock ('Medical Observations and Research'), that, "in knowledge, a junior medical student of the present day is far superior to a Hippocrates or a Sydenham"—we ought to think and judge for ourselves, and not lean too much upon the authority of those who had few of the advantages which we possess.

Spontaneous Origin of Syphilis.—In the opinion of Mr. Holmes Coote, the syphilitic poison is mainly produced by filth and excess, or, in other words, by filth and promiscuous intercourse. This idea is by no means new, for Astruc alludes to those who, as he expresses it, "objiciunt luem veneream sponte oriri ex venere vulgivagâ;" and he laconically replies, "Luem veneream nunquam observatam fuisse ante annum 1494"—a most palpable *petitio principii*, since this was one of the very points at issue, and was not admissible as a valid argument against the other.

Mr. De Meric objects in these words: "This inquiry may, however, appear idle to some practitioners, as we have it stated in certain books that the poison of syphilis may be generated spontaneously. It has also been maintained that frequent promiscuous intercourse, coupled with uncleanly habits, may cause the development of syphilitic ulcerations. If notions of this kind were to gain ground, investigations respecting the intimate nature of the virus—its unicity, duality, or plurality—might well be given up; for spontaneous generation, problematical as it is in natural science, is completely incompatible with the conception we form of a virus or morbid poison:" and he goes on to say, "Nay, we concede a special virus for scarlet fever, influenza, rubeola, and typhus, although we are aware that it must be volatile and unamenable to the senses by any vehicle; so we may, *à fortiori*, look upon the syphilitic virus as having a *bonâ fide* existence."

That the poison of syphilis has a *bonâ fide* existence, when once generated, is no doubt true; but this in no way militates against the arguments in favour of its spontaneous origin. In his essay "On the Zymotic Diseases, Registrar-General's Report on Cholera, 1848-9," Dr. Farr states of syphilis, amongst other diseases: "It must be admitted, with respect to all the forms of these diseases, that the body, in the cycle of external circumstances through which it passes, may run into them spontaneously; for it is impossible to trace them invariably to infectious sources: it is not, *à priori*, more improbable that they, than other diseases, should arise spontaneously, and it is impossible to account for their existence in the world upon any other principle than that of spontaneous origin."

In 'Transactions Epidemiological Society, Sanitary Review,' No. IV., Dr. Riecke states: "All contagia, under certain circumstances, have a primary origin; and even syphilis may be primarily produced. This is a fundamental principle."

Dr. Barker writes: "Nor does the fact of a disease being communicable from one person to another in any way show that the first instance of that disease was not from some external cause—a cause which may possibly have died out, but which, with equal reason, may be supposed as still extant."—('Fothergillian Prize Essay,' 1863.)

The late Dr. Alison, of Edinburgh, believed in the spontaneous origin of scarlet fever and varicella.—('Practice of Medicine.')

Dr. Wood, Professor of the Theory and Practice of Medicine in the University of Pennsylvania, believes that all contagious diseases may arise spontaneously, and brings forward cases of variola, of which he remarks, "It would be difficult to admit the possibility of a contagious cause."—('Practice of Medicine.')

Dr. Tweedie says of typhus: "For example, the possibility of typhus being engendered by overcrowding in infirmaries for the sick, prisons, workhouses, transport ships, and dwellings of the poor, is a fact so well established, that no one in the present day attempts to dispute the statement. We have only to examine the records of epidemic visitations to be satisfied of the truth of this axiom; and under whatever circumstances the disease may have arisen, its propagation by contagion explains its often rapid extension, *a twofold cause being in operation.*"

Dr. Barlow says: "Relapsing fever certainly has much the appearance of a disease originating from marsh poison, the history of which seems to suggest the belief that it is generated by filth and starvation, but that it is capable of reproduction by contagion."

Of erysipelas Dr. Todd writes: "A patient who has received an injury may generate the poison of erysipelas in his own person by exposure to certain deleterious influences; or he may, under similar circumstances, generate this poison in his own body, even when he has not received any wound."—('Med. Gazette,' 1850, vol. xi., N. S.)

Perhaps there is no disease, with the exception of syphilis, the spontaneous origin of which has been so universally denied as measles; yet it would be difficult to account in any other way for the following cases, reported by Dr. Noble, of Manchester, in 'Med. Gazette, 1850, vol. xi. N. S.:—

"Mrs. E. gave birth to her first child on 25th July, 1847, attended by a friend on my account, during my absence from home. I saw both mother and child on my return in a few days, and they seemed doing well. Having taken my leave of the patient in about ten days from her labour, I was summoned to see the infant in three or four days afterwards, and found it covered with measles, attended by fever, and having been preceded by the ordinary premonitory symptoms of coryza and cough. The symptoms declined in the usual way, and in about a week the child was well. I neither saw nor could hear of any other case from which it could have been taken. The mother, intending a probable explanation of the phenomenon, stated that according to the statements of her mother, she and a twin sister had measles also when a fortnight old.

"On the 12th June, 1849, Mrs. E. gave birth to a second child. She did well, and I ceased to visit her at the expiration of about a week.

"On being summoned to attend another member of the family some months afterwards, I was informed that the second child had had measles at the same period after birth, and exactly under the same circumstances as in the former instance. All the inquiries I could make led to a conviction upon my part of the accuracy of the statements that were made. It had not been considered necessary to call in medical aid.

"During the present year Mrs. E. again became pregnant, and I was once more engaged to attend her. She was confined on the 31st ult., under circumstances quite favourable. I was naturally curious to know what would happen with the child when ten or twelve days old, and continued my own personal observation. Measles again became developed accompanied and preceded by slight fever, with mucous irritation of the air-passages. The case was this time but slight, yet it was unequivocal. The infant is now well again. Measles do not prevail in the neighbourhood; nor am I aware of any case from which the contagion could have been received."

The spontaneous origin of similar diseases amongst animals has also been denied, upon, I think, no stronger evidence; but with such avidity are sources of contagion sought for, that they are always found. Nevertheless, Dr. Copland says: "From the facts adduced by Mr. Coleman, Dr. Ashburner, and Elliotson, it evidently appears that glanders in horses may be generated anew when several of

them are shut up together in a confined atmosphere, as often happens on board transports."—('Med. Dict.')

Now, syphilis has been considered glanders in the human subject; and it is exceedingly difficult sometimes for even the most experienced to distinguish one disease from the other, as the following case extracted from Dr. Atlee's notes will show:—"March 1st, 1854.—A patient with double lachrymal fistula entered M. Nélaton's Clinique. This gentleman, after examination, was tempted to ascribe the affection to syphilis. There were ulcers on the palate. On taking his history, it was found that the young man had been caring some horses, and one of them was sick and concealed from the police. The patient became gradually but slowly worse. Nélaton said the case was one of chronic glanders."—('Drysdale on Syphilis.')

In a leading article, 'Med. Times and Gazette,' 1863, it is stated of rabies canina: "Though the disease *may undoubtedly arise spontaneously*, in the vast majority of cases, it is due to the introduction of a specific virus into the system;" and Renault states that the spontaneous origin of rabies is extremely rare" ('Lancet,' 1863), inferring therefore that it does occur.

(To be continued.)

BRIEF NOTES ON MR. J. Z. LAURENCE'S PRACTICE AT THE SURREY OPHTHALMIC HOSPITAL DURING THE PAST YEAR.

By ROBERT C. MOON, House-Surgeon to the Hospital.

DISEASES OF THE CONJUNCTIVA.

These formed by far the great majority of cases treated during the year. The treatment generally adopted, and found to be most successful, was the application of a solution of nitrate of silver (varying in strength from 4 to 30 grains to the ounce, according to the intensity of the inflammation) to the everted eyelids. After a few seconds the solution was washed off with water, so as to prevent any unnecessary and injurious subseqent irritation to the cornea.

Conjunctivitis granulosa has been treated in various ways. Free scarification of the granulations has given immediate relief to the pain, and in a few cases where it was frequently repeated a permanent cure has resulted. The application of the solid nitrate of silver, or the sulphate of copper, to the granular conjunctiva has been in many cases successful. The application of the liquor potassæ to the everted lids has in other instances yielded most satisfactory results. In one inveterate and long-standing case, which had resisted all the above remedies, the granulations were speedily destroyed by touching them with the potassa fusa. The application was followed for some days by acute pain and suppuration, which had subsided by the tenth day, when it was found, on everting the upper lid, that it presented a pale, non-granular surface; only a few vascular granulations remaining at the edge of the palpebral sinus, where probably the potassa fusa did not reach. These granulations, however, afterwards disappeared by touching them with a weak solution of nitrate of silver. This patient was seen about six months after his dismissal from the hospital; his eyelids were then perfectly sound. In all the cases of conjunctivitis granulosa the cornea was more or less affected, excepting two in which the cornea was perfectly clear. One case of *melanotic tumour of the conjunctiva* has been treated during the past year, which deserves a few remarks.

E. H., æt. fifty-two, presented herself with a pyramidally-shaped growth, measuring 4‴ from above downwards, and about the same across at its base, which was attached to the cornea at its lower and outer quadrant, and also to the adjacent scleral conjunctiva, the apex of the tumour being free, and protruding from between the closed eyelids. The growth was soft, somewhat lobed, and of a deep slate colour. For upwards of twenty years there had been a minute brownish spot in the situation of the tumour, but it had only grown large during the last six months. To its inner side were a few enlarged subconjunctival veins leading to the tumour, as well as a large scleral discoloration.

On Jan. 19, 1863, Mr. Laurence removed the tumour with scissors, and on microscopical examination it presented all the appearances of a cancerous growth. When the patient was last seen after an interval of fourteen months, it was found that no return of the growth had supervened, and the eye was in a perfectly healthy condition, merely a small cicatrix at the cornea and adjacent conjunctiva indicating the former attachment of the tumour. An almost identical case is reported by Dr. Steffan, in Zehender's 'Monatsblätter,' ii., p. 81.

Entropion has been treated in three different ways:—1st. By removing simply a small portion of the skin and muscle of the lid parallel to its ciliary margin, and uniting the cut edges by sutures. 2nd. By excising a strip of the cartilage, uniting the margins of the groove thus left, and then bringing together the edges of the integument with silver wire or silk sutures. The third method consists in passing two or three threads, at about the distance of 3‴ from one another, through the skin and muscle of the lid from above downwards, taking care that the counter-puncturation with the ligature needle is made a little above the ciliary margin. The two ends of each ligature are then tied tightly on the outer surface of the lid, and after three or four days the ligatures are removed. This plan has yielded very satisfactory and permanent results, so far as it has been tried at this hospital. In no instance has the operation been followed with suppuration, as is stated to be the case with the method proposed by Dr. Pagenstecher. The following case shows that it is not necessary, as in Dr. Pagenstecher's operation, to include the border of the lid in the ligature, so that the subsequent irregularity and distortion of the edge of the lid are avoided.

CASE.—Thomas C., æt. sixty-four, came with complete ptosis of the right upper lid, and entropion of the lower. There had been partial ptosis of both upper lids for fifty years, from a blow with a cricket-stump, causing a fracture of the right parietal bone (concussion, meningitis, &c.) During the last six months the ptosis of the right upper lid had become complete. Mr. Laurence treated both lids of the right eye in the manner described above. The ligatures were removed in a week, by which time the eyelashes had resumed their normal position, the entropion of the lower lid being completely cured. On looking straight before him, the maximum separation of the right lid was about an eighth of an inch, that of the lids of the left eye being a quarter of an inch. Twice subsequently the operation on the right upper lid was repeated, which has enabled him to open the eyelids to the extent of 4‴, so that the lower margin of the upper lid corresponds exactly with the upper margin of the pupil. No suppuration followed either of the operations.

DISEASES OF THE CORNEA.

Affections of this structure form a very large proportion of the diseases which have been treated at this hospital. Most of the patients suffering from corneitis have been in a debilitated condition, and in the majority of cases a tonic plan of treatment has been found necessary. Warm applications have proved of decided use in many severe cases of corneal inflammation, either with or without ulceration. Where ulceration has occurred, especial benefit has been remarked from the application of a cotton wool compress bandage (Druckverband), the object being, as in the case of ulcers in any other part of the body, to keep the eye in a state of perfect rest, by which means the most favourable conditions are presented for the natural repair of the loss of surface. In a few cases great relief was obtained from the local abstraction of blood, and the application of blisters behind the ears. A case of *Congenital Double Corneitis* has been seen during the last year, of which a report is published in the July number of the 'Ophthalmic Review.'

Our attention has been directed much of late to the marked decrease in the sensibility of the cornea when that structure has from any cause become opaque.

Cataract Operations.

In addition to the ordinary method of extraction, the plan of excising a portion of the iris, previous to the extraction of the lens, as proposed by Dr. Mooren, has also been practised in three cases of cataract. An interval of about a month was allowed between performing the iridectomy and extracting the cataract; and although each of these three cases presented difficulties of an unusual kind, they all recovered without any subsequent inflammation, and with sufficient sight to be able, by the aid of proper glasses, to read tolerably small type.

Case 1.—J. L., ætat. sixty-four. *Right Eye:* Operated on at another hospital for cataract thirteen months ago. *Left Eye:* Fully formed senile cataract; good perception of light; iridectomy downwards; after which there was hardly any irritation. In about a month afterwards, Mr. Laurence extracted by the downward section. After the section of the cornea, owing to some spasm of the lids, a quantity of vitreous escaped, along with the still encapsuled lens. The eyelids were at once closed, and a cotton wool compress-bandage was applied. The case ultimately made an excellent recovery.

Case 2.—J. M., æt. sixty-nine; sight has been failing him for about a year. *Right Eye:* Mature senile cataract; good perception of light; tension normal. *Left Eye:* Incipient cataract; can only read No. xxx. (Snellen) at about a foot. Iridectomy downwards in right eye; extraction a month later. In this case the cataract knife was withdrawn before the section of the cornea was quite completed, so that a narrow bridge was left at its lower margin which was divided with scissors after the capsule had been opened; perfect healing. After freely dividing a few capsular bands which occupied the area of the pupils, he was able with 2½ to read No. 8 and almost No. 6.

Case 3.—S. B., æt. seventy-three. The sight of right eye has been failing for six months; that of left for nine months. *Left Eye:* Has good perception of light. *Right Eye:* Reads No. 18 quite close to eye; cataract of both eyes, more advanced in left; large iridectomy in left eye; extraction a month later. In making the flap some difficulty was experienced in consequence of the patient spasmodically closing the lids, and the incision was enlarged with a keratome. The cortical portion of the lens being soft prevented its complete removal, notwithstanding which the patient recovered excellent vision, being able to read a very small type with an appropriate glass.

A large number of soft cataracts have within the last few years been operated upon at this hospital with the needle, the majority of which have terminated successfully; but in a few instances it was subsequently found necessary to extract the cataract completely by the linear method, in consequence of some particles of the opaque lens matter finding their way into the anterior chamber, and there setting up serious irritation. These cases have, in some instances, been followed by acute iritis, and even by complete blindness. Having experienced the great danger to which the ordinary method of operating was liable, when the lens was too freely divided, Mr. Laurence was induced to try the plan of dividing it *sub-capsularly*. After fully dilating the pupil with atropine, he introduced the needle through the sclera on a plane parallel with the iris, then punctured the capsule, and passed the needle on in the direction of the centre of the lens, when he freely divided the lens-substance in every direction, taking care that no second puncture was made in the capsule, in order to prevent the possibility of any flocculi passing into the anterior chamber. No swelling of the lens, or passage of any particle of its substance into the anterior chamber, followed this method. As yet we have not had a sufficient number of cases to furnish statistics on the value of this sub-capsular operation; but its intention is to combine a more speedy absorption of the cataractous lens than is attainable by frequently-repeated divisions with the needle, and to avoid multiplications of the operation; the risks involved in a free division of the lens and capsule together being at the same time avoided.

During the past year, we have had three cases of *Paralysis of Accommodation*. These, with two others which have been admitted since, are fully reported in the 'Ophthalmic Review' for April, 1864. Two of the cases seen during 1863 were from traumatic causes: the one resulting from a blow on the eye with a lemonade cork, and the other from a piece of putty striking the eye with great force. Each of the patients to whom these accidents happened had been previously hypermetropic, but until the time of the injury they had been able to correct this defect by a voluntary effort of the accommodation. In three of the reported cases, the iris, as well as the ciliary muscle, was completely paralysed; in the fourth case, it was only partially so; and in the fifth, the pupil was contracted, and the iris acted with the greatest activity. For further particulars respecting these cases, and a detailed account of the experiments with the Calabar bean, vide the report referred to above.

A case of amaurosis, dependent on effusion into the orbit or cranium, has been reported at length in the Medical Circular for January 13, 1864. The prominent symptoms were:—Complete loss of vision in the affected eye, accompanied with slight protrusion and divergence of the globe, the mobility of the eye being greatly diminished, and the pupil becoming widely dilated when the other eye was covered. She had been subject to periodical attacks of violent pain in the head, with obstinate constipation, for a long time previously, but no abnormal appearance of the fundus oculi could be discovered with the ophthalmoscope. Within three months from the time she came to the hospital, the vision and movements of the globe had become completely restored, under a brisk purgative plan of treatment.

HOSPITAL REPORTS.

WESTMINSTER HOSPITAL.

On Tuesday we paid a visit to this hospital, and saw the following cases:—First, a middle-aged man suffering from scabies, which thickly covered the chest, abdomen, inner sides of the thighs, and the back, but more especially the first two regions. He was an out-patient, and was under the care of Mr. Heath, who, in the presence of the class attending the hospital, took the opportunity of pointing out the rarity of this eruption as occurring upon the face, and the frequency with which it is met upon the front of the body, especially of the abdomen.

The treatment to which the man was submitted was that by external application only, the lime and sulphur lotion being prescribed. The manner in which this remedial agent should be used is very simple:—The patient is made to take a warm bath, and while in it to wash himself thoroughly with the best yellow soap. Petroleum soap is an excellent kind for the purpose. Having well dried the surface of the body, he should then have each scabietic spot mopped with some of this lotion, and the parts so treated should be allowed to become completely dry: the bath and lotion may be used in the evening or at night; the patient should afterwards sleep in a blanket, and on the next day the bath must be repeated, and the entire of the body cleansed; when, if the lotion be properly applied, the disease will, in the majority of cases, be found to be wholly stayed, the acarus having been destroyed.

This is a decided improvement upon the old method of treatment, than which it is far more rapid in its results, being speedily effective. We have tried it ourselves in very many cases, not alone of simple scabies, but where this eruption is present at the same time with syphilitic disease.

The second case, and which also was under the care of Mr. Heath, as an out-patient, was a woman about the middle age, and mother of a family. She was of a spare habit, and had a peculiar delicate and sad expression of face, and also a cachectic appearance, indicative of either an exhaustive and long-standing ailment or of a malignant affection. Her history was: Some time previously she presented herself at the hospital with a tumour of a malignant nature in the right breast. This she was advised to have removed before the ulcerative process should supervene; but she declined to have any surgical procedure put

into practice, and preferred to run the risk of a rapidly fatal termination, to which, indeed, at the time of her receiving advice, the disease seemed to be hastening. In the course of time—about twelve months had elapsed—the integument became broken by the ulcerative process, which, as it continued, tended to the removal of the tumour. There was found at the present examination to be a hard, puckered cicatrix surrounding the nipple, the base of which was involved in the cicatrix, whereas the apex rose prominently from it. The colour of this cicatricial tissue was of a deep red hue, with somewhat of a purplish tinge, which was pathognomonic of the kind of disease and of the patient's condition of health. This was an instance of natural atrophy of a cancerous breast, or rather, to speak more correctly, of a cancerous tumour of the breast.

The daughter of this patient, who was about eleven years of age, had *strumous* enlargement of the glands of the neck. She was also of a very delicate general habit.

CASE III. was likewise an extern patient, under the care of Mr. Heath; it was a child aged fifteen months, and the offspring of a delicate mother, who, to save herself expense, had continued to nurse the patient up to the present time. There was great general debility, evidently because lactation had been persevered in for too long a time; and the mother's milk had become so deteriorated in quality, so altered in its nutritious properties, as to have been, no doubt for some time past, not only insufficient for nutrition, but positively injurious. As a consequence of this malfeeding, struma had been engendered and the child injured in health, perhaps permanently. The entire glandular system was enlarged, and besides this evil, the glands of the right axilla had taken on suppurative action, had burst, and poured out no small quantity of purulent matter.

The mother was enjoined to at once give up nursing, and the child was put upon the syrup of the iodide of iron.

CASE IV. was a nævus, which had been tied by Mr. Heath, the ligature being allowed to remain constricting it for not longer than twenty-four hours. The patient was only five months old, and not of a very strong habit, but yet no unfavourable symptom had set in after the operation; the nævus, which had originally covered an area of about the size of a shilling, or even a somewhat larger surface, was now very much diminished, and was gradually contracting itself as the ulcerated and sloughy spots had taken on a healthy and healing action. Mr. Heath thought that a more rapid and effectual destruction of the nævoid tissues might be obtained by leaving the ligature constricting them for forty-eight hours, instead of the twenty-four, which latter time had elapsed between the application and removal of the ligature, in the present instance.

The nævus was situated on the top of the head, and seemed to have engaged deeply the structures composing the scalp; it lay somewhat in front of the posterior fontanelle.

CASE V.—A little boy, aged about ten, of delicate strumous habit, and with the features so characteristic of that peculiar diathesis, presented himself as a patient from abscess of the right tonsil. Having swathed a sharp-pointed bistoury halfway up its blade, when the boy's head was thrown well back, the mouth opened as widely as it would admit, and a good light made to bear upon the part about to be operated on, Mr. Heath made an incision into the tonsil—at its upper part, that is, where it joins the velum and arches of the palate—and gave exit to the purulent matter collected in it. He pointed out to his class the impropriety of plunging the knife into the tonsil, or of directing the instrument outwards, or outwards and backwards, or of burying it too deeply in the tonsil; and he at the same time took opportunity to dwell upon the fact that the carotid was not endangered, if the surgeon made his incision at the upper part of the abscess, which was, indeed, some distance from the artery just named.

CASE VI.—A middle-aged woman, with a specific or syphilitic ulcer in the popliteal space. There had been considerable hardness and a brawny condition of the entire limb for some distance around the ulcer which itself presented an appearance as though a circular piece of the soft tissues of the ham had been gouged or scooped out. The staining of the margins of this ulcer and of the integument around it, or rather, the alteration in its natural colour, was of that nature which at once showed the true character of the ulcer and of the taint with which the system was contaminated.

The treatment was that by the internal use of bark and nitric acid, at the same time that there was applied to the ulcer itself the lotio flava, which Mr. Heath prefers, in such cases as the present, to the lotio nigra. The strength of the yellow wash was gr. j. of the corrosive sublimate to ℥j. of lime water.

After our visit to the extern patients' department, we adjourned to the operating theatre, and the first case of which we had an opportunity of witnessing the treatment was that of a middle-aged man, of robust build, stout habit of body, and with a short, thick neck: Some time since, this patient had been attacked with disease of the bone of the lower maxilla; as a sequence of this affection abscesses had formed in and about the lower part of the face and in the neck; they had burst, discharged themselves, and had then given rise to unhealthy sores and sinuses. Chloroform being badly borne—it had occasioned great congestion of the veinous system of the neck and face, and consequent empurpling of these regions—was not administered to its full extent.

Having inserted a probe into the sinuses, and having ascertained that there was dead bone at the bottom of them, Mr. Barnard Holt passed into the principal one—the largest and that which led most directly down to the diseased bone—the sharp-pointed bistoury, opened it up, made quite certain of the presence of dead osseous structure, and endeavoured to get away some portions of it.

The object of the present procedure was rather to open up a free channel and aperture of exit, so that Nature might throw off the dead tissues, than to remove them by any of the more severe aids of surgery.

CRITICAL AND ANALYTICAL REMARKS ON THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XXII.

DIGITALINUM.—The active principle of digitalis is now, for the first time, introduced as an officinal remedy; and although scarcely anyone ventures to prescribe it, and it will probably be omitted in the next Pharmacopœia, we may devote a small space to an account of it. The mode of preparing digitalin is, shortly, as follows:—A spirituous extract of the powdered leaves of digitalis is first made; this is dissolved in water and a little acetic acid, and the solution is partly decolorized by animal charcoal. The acetic acid is now neutralized with ammonia, and thus a solution of acetate of ammonia and digitalin is obtained. From this solution the digitalin is precipitated by means of tannic acid. After washing with water, the precipitate is rubbed with litharge, which combines with the tannic acid and sets the digitalin free. The latter is then taken up with spirit, the solution is treated with animal charcoal, filtered, and evaporated. The residuum is the digitalin, contaminated, according to Walz, with some other neutral bodies allied to it, which are removed by washing with ether, in which digitalin is insoluble.

So obtained, digitalin forms a light and tolerably white porous mass, which separates into scales. The Pharmacopœia says it is inodorous; but all the specimens we have met with have had a faint smell of digitalis: the taste is intensely bitter. The process just described shows that it is readily soluble in spirit, but almost insoluble in water and ether. It dissolves in acids, but does not form with

them neutral compounds. Digitalin is, in fact, a glucoside, which, when boiled with dilute sulphuric acid, splits up into glucose, and a body to which the name *digitaliretin* has been given :—

$$\underbrace{C_{54}\,H_{45}\,O_{30} + 4\,HO}_{\text{Digitalin.}} = 2\underbrace{(C_{12}\,H_{12}\,O_{12})}_{\text{Glucose.}} + \underbrace{C_{30}\,H_{25}\,O_{10}}_{\text{Digitaliretin.}}.$$

The chemistry of digitalis, however, cannot be considered as settled, since Walz and Kosmann, to whom we owe most of our knowledge concerning it, are not agreed, either as to its composition or decompositions.

Digitalin is a most powerful poison, and considerable attention has been drawn to it by a recent murder in Paris. Some account of the means of detecting it was given in the Medical Circular for July 6, but we may add a few more reactions which are said to be characteristic. Sulphuric acid produces with it a reddish brown colour, which, on exposure to the vapour of bromine, changes to a deep violet. Ammonia gives a rose-red colour which changes to brown. Hydrochloric acid, as mentioned in the Pharmacopœia, produces a green colour.

The dose of digitalin is said to be one-thirtieth of a grain; but it is notorious that the imported samples vary greatly in activity.

Ferri Sulphas.—In noticing the different compounds of iron contained in the British Pharmacopœia, it will be convenient to depart from the alphabetical order there adopted, and we therefore commence with the Sulphate. It will be remembered that the London College gave a process for Sulphate of Iron, which consisted in purifying green vitriol or the sulphate of iron of commerce. This method has been discarded, and a process is now given for preparing the salt directly from the metal. The only form of metallic iron contained in Appendix A is iron wire, which is described as annealed or binding wire. We believe this is one of the purest forms of iron that is readily attainable.

The sulphate is prepared by taking iron wire, sulphuric acid, and distilled water, putting them in contact, and, when the disengagement of gas has nearly ceased, boiling for ten minutes and then filtering the liquid through paper. After the lapse of twenty-four hours, the crystals which have deposited from the solution are separated, dried on filtering paper, and preserved in a stoppered bottle.

The reaction which occurs in the process is very simple; the iron, acting upon the diluted sulphuric acid, displaces the hydrogen of the water, forming a protoxide of iron, which, united with the sulphuric acid, constitutes the sulphate :—

$$HO, SO_3 + Fe = Fe\,O, SO_3 + H.$$

The operation is best conducted in a porcelain dish or open vessel, as the Pharmacopœia directs, so that the liberated hydrogen may at once pass off.

Sulphate of iron crystallizes with seven atoms of water. It is described in the Materia Medica as occurring in oblique rhombic prisms, of a green colour and styptic taste; insoluble in spirit, soluble in water. The solution gives a white precipitate with chloride of barium, and a blue one with the ferridcyanide of potassium, and on exposure to the air gradually becomes turbid, depositing a reddish brown sediment. Sulphate of iron when quite pure and recently prepared has a decidedly pale blue tint, which becomes green by keeping or by exposure to the air. This salt varies slightly in the facility with which it is acted on by the air, depending on the state of the solution from which it has been crystallized. Commercial sulphate of iron is commonly crystallized from a strongly acid liquid. The ochry powder which forms upon the surface of the crystals, and is also deposited from a solution of the salt which has been long kept, consists of a basic sulphate of the peroxide. The oxygen of the air converts the protoxide of iron in the salt into peroxide, which requires a larger amount of sulphuric acid to form a soluble sulphate than is present; consequently a portion separates out as an insoluble basic salt.

The Pharmacopœia directs that an aqueous solution of sulphate of iron shall give no precipitate with sulphuretted hydrogen, and one nearly white with ferrocyanide of potassium. The absence of any precipitate by sulphuretted hydrogen shows that the salt is not contaminated with copper, which is sometimes the case, and also, to a certain extent, indicates its freedom from persalt. Sulphuretted hydrogen does not precipitate either the proto or per salts of iron, but it acts upon the latter, reducing them to the state of proto salt with the simultaneous liberation of sulphur. Consequently, the formation of a white precipitate of sulphur indicates the presence of a persalt. It is exceedingly difficult to get protosulphate of iron which shall give a white precipitate with ferrocyanide of potassium. Even when it is got the effect is only momentary, for oxygen is absorbed so rapidly that the precipitate immediately assumes the blue tint due to a persalt; therefore it is described by the Pharmacopœia as nearly white.

Ferri Sulphas Granulata.—This preparation has been taken from the Dublin Pharmacopœia, and the process which was there given has been, with a slight modification, adopted. Granulated sulphate of iron is prepared by pouring a solution of pure sulphate of iron into spirit; the salt being insoluble in the latter menstruum, is at once precipitated in the form of minute crystals. The first part of the process given is the same as for sulphate of iron. Four ounces of iron wire, four ounces of sulphuric acid, and a pint and a half of distilled water are put into a dish, and when action has ceased, the liquid is boiled for ten minutes, and then filtered into a jar containing eight ounces of rectified spirit, stirring the mixture until the salt has separated out. The minute granular crystals so obtained are transferred to filter paper, dried by exposure, and then preserved.

The Pharmacopœia represents this salt as having the same composition as the ordinary crystals of sulphate of iron, and assigns to it the formula $FeO, SO_3 + 7HO$. Some exception has been taken to this, and it has been said that the salt contains less than the seven atoms of water. This statement is supported by the fact that alcohol is capable of abstracting the water of crystallization from sulphate of iron to such an extent, indeed, as to deprive the salt entirely of its colour. It might be inferred, therefore, that as the salt is precipitated from its solution by spirit, a portion of its water of crystallization would be at the same time removed. Possibly with the first few drops of solution which enter the spirit this is the case; but it must be remembered that a pint and a half of solution are added to eight ounces of spirit: the proportion of alcohol, therefore, must be far too small to exert any dehydrating influence on the salt itself. The Pharmacopœia formula is, moreover, sufficiently supported by the analyses which have been made of the granulated salt.

This form of sulphate of iron is one of the purest and most definite which can be obtained, for being precipitated from solution, it is more perfectly freed from the excess of acid, persalt, &c., than it could possibly be by the ordinary process of crystallization. It is described in the Materia Medica as occurring in small granular crystals of a pale green colour and mildly styptic taste, soluble in water, and insoluble in rectified spirit. Why this salt should be "mildly styptic," while the ordinary sulphate is "styptic" is not very obvious.

The tests are identical with those for sulphate of iron.

Ferri Sulphas Exsiccata.—Dried sulphate of iron is prepared by exposing the crystallized salt in a porcelain capsule to a moderate heat, which may be finally raised to 400°F., until aqueous vapour ceases to be given off. By this process six out of the seven atoms of water in the salt are expelled, and a white powder is obtained. By the application of a still stronger heat, the last atom of water might be expelled, and the anhydrous salt obtained. At a full red heat complete decomposition of the salt ensues, sulphuric and sulphurous acids passing off, and peroxide of iron remaining behind—

$$2\,(Fe\,O, SO_3) = Fe_2O_3 + SO_3 + SO_2.$$

Eighty-five grains of the dried sulphate ($Fe\,O, SO_3 + HO$) are equal to 139 grains of the crystallized salt.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 3, 1864.

THE CLOSE OF THE PARLIAMENTARY SESSION.

The termination of another Parliamentary Session naturally leads us to reflect upon the relations existing between the Medical Profession and the Legislature, and to inquire how far the interests of our body have been promoted or retarded, or otherwise affected, during the season which has just closed. If there is not much reason for congratulation on any victory achieved, there is not any regret to be expressed for hopes that have been disappointed; in fact, as we expected nothing, we may be grateful if we have received only a little.

In the first place, we have cause to be thankful that, although the condition of the Army Medical Department has not been materially improved, the course of bad legislation in respect to this service has been retarded in a manner as satisfactory as it was unexpected. Only last week we recorded our feeling of regret that a short Bill, entitled the India Medical Service Bill, and which had for its object the abolition of competitive examination for the Medical Service in India, had been allowed to pass its second reading in the House of Commons. We need scarcely remark that when a bill has passed its second reading, and has gone through committee, it is looked upon as virtually having passed the House; and such was considered to have been the fact on Monday last, when we went to press. But, on the evening of that day, Mr. Hennessy, who had offered a strenuous opposition to the bill in all its stages, renewed his opposition on the occasion of the third reading, and rallied round him many of the independent members of the House; and notwithstanding the support of the bill on the part of the Government, he succeeded in defeating it by a majority of two—the number of those who voted on both sides being considerable, taking into account the advanced state of the Session and the very little general interest excited by the bill itself. We are most thankful to record this defeat of the Government, whose only object in bringing forward the measure appears to have been to strengthen the hands of the authorities at the Horse Guards in resisting the just and reasonable demands of the Medical Profession in relation to the Army Medical Service.

As it is hardly worth while to slay the slain, the bill may perhaps better be consigned to oblivion; but we cannot help remarking that Sir Charles Wood had a most uphill task in supporting the measure, and that, as soon as he began to explain its provisions, he involved himself in such a mesh of absurdities and equivocations as to render its rejection inevitable. In fact, there can be no reasonable doubt that this little bill was intended quietly to be thrust through the House, in the thin and languid attendance common at the close of the summer; and the Horse Guards would then have had another triumph over the Medical Profession. But this time they are disappointed; and if they intend still to resist the pressure made upon them in reference to the Army Medical Service, they must adopt some other kind of tactics than those exhibited in the concoction of their India Medical Service Bill.

In other respects, the Army Medical Service remains in the same position as before. A large number of vacancies exist, and candidates are deficient; and of those who offer themselves for the competition, many fail to pass the examination, and those who do pass are mostly in the third class. That this result is in great measure to be attributed to the dissatisfaction existing against the Army authorities, is indubitable; but it is not true that the Profession is so overstocked as to render the Army Medical Service under any circumstances a very desirable boon to the Medical aspirant of the present day. The real fact is, that the junior ranks of the Profession are not at present overstocked, and the number of medical students is smaller than it was some years since, while the demand for young medical men is greater: but the necessity of a better education, especially in the preliminary branches, and the stringency of competitive examinations, have deterred many young men from entering upon a medical career, the emoluments of which are unlikely to remunerate them for the expenses they must incur and the time they must wait before profitable employment can be expected.

While the Medical Service of the Army is thus unable to attract the better class of students to its ranks, the Poor-law Medical Service is as much sought for as ever, chiefly, perhaps, because it is a home service; and the Poor-law authorities, both national and local, are able to make what terms they please with the Poor-law Medical Officers. If a Medical Officer remonstrates with the Guardians, he is told he may resign, or he is dismissed, and a dozen competitors spring up for the vacant post, and any attempt to procure a more adequate compensation for Poor-law Medical services is necessarily frustrated by the competition to which we allude. The patient and laborious efforts of Mr. Griffin to obtain something like justice to his brother-officers has been only partially successful; but still, the recognition of the claims of the Poor-law Medical Officers to consideration at the hands of the State has been obtained, and we have reason to be thankful for what has been already accomplished; while at the same time we hope that, by continuing the contest, still more may be achieved.

All attempts to exterminate the plague of small-pox by a thorough and well-devised scheme of general national Vaccination have been frustrated by the listlessness of the Government and the Legislature. Although it has been proved over and over again that efficient vaccination has never yet been carried out in this country, and that the Poor-law Guardians are wholly incompetent to superintend satisfactorily the performance of the operation, no steps have yet been taken to place matters on a better footing so as to protect the community. This is, perhaps, the more to be wondered at, since in the Session which has just closed, certain compulsory measures have been taken in respect to another disease, the victims of which are not the

feeble and the innocent, but the debauched and the depraved. In the case of the so-called Contagious Diseases Prevention Bill, powers are conceded to the police and the magistrates of a most stringent character, and totally inconsistent with the maintenance of that liberty of the subject which is the boast of our country. But it is argued—and not without reason—that liberty should not be allowed to degenerate into licentiousness, and that persons afflicted with disease ought not to be permitted to disseminate a physical pest among their neighbours. This is all very true, but in the instance in question, the community may avoid the pest, if they only take proper care to lead a virtuous life: while in the case of the small-pox contagion, the public is made involuntarily to pay the penalty of the neglect of the Legislature. The explosion of the fallacy that people are at liberty to propagate disease has, however, been witnessed in this case of the attempted prevention of syphilis; and we may reasonably hope that some day our helpless infants and children will be protected from small-pox, and thus receive the same paternal care at the hands of the Legislature as that which is accorded to our soldiers and sailors, in protecting the latter from the consequences of their own indiscretions.

SUMMARY OF THE WEEK.

THE LONDON COLLEGE OF PHYSICIANS AND THE APOTHECARIES.

The College of Physicians has determined not to grant the *ad eundem* diploma to the holders of Licences of the London Apothecaries' Society; and in this determination we think that the College has shewn a due regard to its own dignity. A more absurd proposition than that of requiring the College to accede to such a request, has, perhaps, never been made. If, indeed, the College of Physicians was a State Institution, invested with legal power to concentrate the whole mass of the Medical Profession within its jurisdiction, such a step as that which it has been requested to take, would be not only desirable, but would be a mere act of justice. But the College of Physicians, although the highest Medical Corporation in England, is only one out of many similar bodies empowered to grant Diplomas and Licences to practice Medicine, and the attempt to swallow up all the Members of the Profession could only be regarded as indicating either an avaricious desire to gain money at the expense of respectability, or a love of popularity at the risk of ultimate confusion. If, too, it is considered that the Licentiates of the Apothecaries' Society of London have a claim upon the *ad eundem* diploma, why have not the Licentiates of the Dublin Apothecaries' Society the same claim? And why, again, should the members of the London, or any other College of Surgeons, be disentitled to the same concession? And why, *à fortiori*, should the Graduates of Universities be excluded from the same boon? If, again, Licentiates of the Society of Apothecaries' of London are to be made, for a money consideration, licentiates of the College of Physicians, why, in the name of common sense, are not all the Members of the College of Physicians to be made Fellows?—why should there be any distinctions in the College at all? If the Fellowship, and the Membership, and the Licence of the College of Physicians are desirable distinctions (and we do not deny that they are so), they are desirable because there is some difficulty in obtaining them, and in the case of the two latter, because a certain amount of intellectual labour is essential to their acquisition; but what value can be attached to an *ad eundem* licence, available for all comers who have some ten or fifteen shillings in their pocket? As we have just remarked, if the College was a State Institution, empowered to over-ride all the Medical Corporations in the Empire, like the School of Medicine in France and other despotic countries, it would be only fair to allow all Medical men holding degrees or licences to inscribe themselves as members by a nominal payment, and thus secure to themselves a suitable professional position; but however respectable the College of Physicians may be, and however justly its Fellows and Members may value the privilege of being connected with it, still there are many persons who may think just as highly of their own Alma Mater, although it is not situated in Pall Mall, London. The prestige of the College of Physicians has hitherto depended (with the exception of the year of grace, or disgrace, when its diplomas were sold at ten guineas a piece) on the value it has hitherto set upon the distinctions it conferred, and on the high character of the examinations it has instituted. It is well that it has shown its resolution to maintain this high position, and to repudiate a course of action which might have filled its coffers with a few hundred guineas, but would have reflected a lasting disgrace upon itself, and by comparison would have elevated the rank of other corporations which it sought to overthrow.

THE MEDICAL PROVIDENT FUND AND THE BRITISH MEDICAL ASSOCIATION.

The establishment of a Medical Provident Fund, for the purpose of assisting Medical men in time of sickness, and of providing for their widows and orphans in the case of their death, has long been a desirable object with the members of our Profession, and more especially with those residing in the provinces, to whom the provisions of the Society for the Relief of the Orphans of Medical Men in London and its vicinity, are of course inapplicable. The proposal to establish such a fund was considered last year at the meeting of the British Medical Association at Bristol, and the subject will again be brought forward and discussed at the forthcoming meeting of the same Association which commences its proceedings this day at Cambridge. We have received a great number of communications on this subject, which we think is one of the deepest importance to our Profession, but many of the writers intimate a fear that very little will be accomplished at the Cambridge meeting, owing to the great pressure of other business, and to the fact that the members will be absorbed in the pursuit of amusement. It is also suspected that the leaders of the Association are lukewarm on the subject,

and that, in attending to their own interests or pursuits, the claims of the Provident Fund will be disregarded. It is therefore suggested that, without placing much confidence in the result of the Cambridge meeting, another meeting should be convened in London in October next, to organise a plan of operations. We think it right, however, to state that the Report of the Medical Provident Fund Committee will be read at the Cambridge meeting on Friday morning next, and Dr. Richardson, the Chairman of the Committee, has published the following letter to the members of the Association :—

To the Members of the British Medical Association.

FELLOW ASSOCIATES,—I beg specially to call your attention to the fact, that the Report of the Medical Provident Fund Committee will be read at the Cambridge meeting on Friday morning next.

The Report will, I hope, show demonstratively that a Provident Fund, capable of exercising the most useful influence in the Profession, may be easily worked in connection with the Association; and it will further incidentally suggest the question, whether it would not be advisable to obtain for the Association a Royal Charter of Incorporation.

Under these circumstances, it may be fairly assumed that the discussion on the Report will be the leading feature of the meeting at Cambridge; and that, on the decision of the meeting, results of immense moment in our future will rest.

May I, therefore, urge on all members of the Association who may come to Cambridge, to let nothing hold them from their attendance on Friday morning; and may I also ask members who are in doubt about coming, to treat, for once, "their doubts as traitors," and to join their brethren.

I remain, fellow associates,
Your faithful friend,
B. W. RICHARDSON.

12 Hinde street, W., July 28th, 1864.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. GEORGE JOHNSON concludes his "Lectures on the Laryngoscope," delivered before the College of Physicians. He points out the applications of the instrument in throwing light upon the causes of hoarseness and aphonia, and shows how warts and tumours are often detected upon the vocal cords, and how tubercular and syphilitic ulceration of the larynx are also often revealed by the same means. The general use of the instrument, by detecting organic disease of the larynx, will often obviate the use of drugs, and at least spare the patient much useless medication; while by indicating removable disease, a cure may be often effected by surgical proceedings. Dr. Johnson, in conclusion, cautions the Profession not to trust too far to the instrument so as to treat the local disease exclusively, because the affection of the larynx may be merely a coincidence or a consequence of constitutional disorder, which must be treated by general remedies.——Dr. G. M. HUMPHRY, of Cambridge, continues his "Surgical Observations," his present subject being "Stone in the Female." He prefers the operation of extraction from the bladder by means of forceps, the urethra being previously dilated by means of cat-gut bougies, introduced gradually in greater and greater number, until the urethra is sufficiently patent to admit the forceps. Sometimes bone, teeth, and hair have been extracted from the female bladder, and their presence in this situation may perhaps be accounted for by supposing that they are derived from an ovarian cyst, which has ulcerated and discharged its contents into the bladder.——Mr. E. W. POLLARD communicates a paper "On the Treatment of Syphilis by Mercurial Vapour." The plan consists in softening the skin by producing gentle diaphoresis previously to employing the vaporised calomel, which is applied in a carefully-constructed box, where the calomel is volatilized at a regulated temperature with the vapour of water and the sublimed particles are equally diffused and deposited on the person of the patient. As inhalation is not always necessary, the head is excluded. Several cases are related, in which the use of this mercurial bath was attended with great success.——Dr. DANIEL MACKINTOSH contributes some notes "On Three Persons Struck by Lightning." The occurrence happened in May last, two of the persons recovering, and one being killed on the spot.

'MEDICAL TIMES AND GAZETTE.'

Mr. WHARTON JONES, of University College, continues his lectures "On Iridectomy and Glaucoma," the second of the series being, in the present number of the journal, brought under notice for our consideration. In summing up the contents of his last paper, Mr. Jones mentions that glaucoma is really a condition of general *venous* congestion of all the structures of the eye, but more especially of the retina and choroid; while there is a pallid condition of the parts traversed by arteries, owing to the constriction of these vessels. The retinal venous radicles are all of them varicose and sacculated; capillaries are not found in the same state; the constricted arteries, however, *seem* to have an increase in the thickness of their walls; this is not a real thickening, but is merely the result of a contraction of their circular fibres, and when the spastic tension of the vessels is relieved, there is synchronously with the relaxation a thickening in the walls. The sacculated appearance of the veins is dependent upon the contraction of their coats in some places, and their dilatation in others. There may be, however, no dilatation; the vessels, where not contracted, merely preserving their wonted calibre, and causing a semblance of true dilatation by comparison with the contracted parts. The cause of the venous congestion is a stasis of the blood-corpuscles in the arteries from constriction of the coats of the latter, by which diminution in the size of the bore of the vessels, the *vis a tergo* is insufficient for purposes of propulsion. Understanding the pathology of glaucoma, we can easily comprehend the injurious effect of atropia or belladonna, these agents tending to intensify the contraction of the circular muscular fibres of the arterial coats. Belladonna stimulates to contraction rather than paralysis to dilatation. The immediate sequence of retinal and choroidal venous congestion is intra-ocular distension, which becomes aggravated by an increase of the intra-cellular fluid of the vitreous body. In antero-internal inflammation, distension takes place in the anterior

segment of the eye-ball; in the opposite form of inflammation, the converse holds good—the anterior segment is diminished in depth, the iris and lens are pushed forwards, and the papilla optica becomes more excavated, owing to a forcing backwards of the nerve into its sheath, a certain degree of atrophy of the nerve itself, and a bulging forwards of the retina by the congested and thickened choroid. The hardness of the eye-ball in this affection arises both from intra-distension and from morbid alterations in the sclerotic. Though this disease is almost essentially chronic, yet it may be sometimes acute, and may be of as different degrees of variety as any other malady. There may be intra-ocular hæmorrhage in the course of the ailment. An account of the condition of a patient operated on for glaucomatous blindness concludes the lecture.——Dr. Harley's fifth lecture is "On Hippuric Acid." In the beginning of his discourse, allusion is made to the importance of the chloride of sodium as a most common ingredient in the composition of every human organism at one time, and in certain tissues increasing solubility at another time, and in other tissues behaving itself as an antiseptic. It prevents the coagulation of the fibrin of blood, and in a certain measure gives to the blood-corpuscles their peculiar colour, according as it occasions them to be bi-concave or bi-convex. Its amount in the human economy is subject to very great varieties—its absence is, indeed, an inordinate want; when it is taken in proper quantities it tends to fatten; when in excess it acts contrariwise. Admitted into the system in any way, it is rapidly eliminated by the saliva, mucous membranes, and the kidneys; in the muscles, the chlorine, instead of being combined with a soda salt, is united with a potash one. Lehmann says it tends to cell-development; without doubt it causes excretion of urea, and that, too, in large quantities. In cases of starvation, none can be detected in the urine. It acts as a valuable tonic by forming muriatic acid in the stomach. The average amount passed is 77·5 grains. In disease, as in health, it varies very much as to the quantity excreted. In diseases attended with exudation, there is diminution or absence of the chlorides; such a condition exists in pneumonia. The sputa, however, contain it largely in such instances as these. From his closing remarks, it is evident that Dr. Harley considers this combination of chlorine and soduim may be used in some affections as a remedial or palliative agent.——Dr. Laycock contributes a paper "On the Treatment of Delirium Tremens and of Delirium in Fevers." The object of the communication is to defend the "rational" and "expectant" method of treatment, which he advocates as preferable to the empirical and heroic plans. It is shown that alcoholic stimuli are of avail, and should be used in asthenic delirium. It is advisable to abstain from the use of opium, or of any of its salts, in the case of the sleeplessness of fever, even when such want of rest may have continued for even more than five or six nights in succession.——Dr. Ogle, of St. George's Hospital, communicates "Cases of Softening of the Brain and Spinal Cord;" the present article being a continuation of former papers on the same subject.——Mr. Bulley has contributed "Clinical Notes and Observations on Hard Nodulated Tumour of the Tongue, apparently of Cancerous Nature, which disappeared under the Use of the Galium Aparine." The patient, a married woman, æt. sixty, had noticed the growth only five weeks previous to her admission into hospital, and during that time there was an increase in the size from that of a hemp-seed to that of a marble; it lay imbedded in the right side of the tongue, and not more than an inch from the apex; was nodulated, and with the feel peculiar to scirrhous growths; was painful as well as tender, and at times the pain assumed a throbbing character. The patient had lived well, but had been at no time what might be termed a free liver; there was no apparent cachexia, nor any history of cancer; the tumour had latterly taken on rapid growth. She was ordered ʒjss. of a fluid extract of galium aparine twice daily, and also a lotion of the same. The most nutritious diet was likewise given. The tumour entirely disappeared; the tongue resumed its natural structure and appearance. The galium (cleavers) is a popular remedy for scirrhus; it has proved useful in professional hands, not alone as antagonistic to cancer, but in epilepsy and certain obstinate skin diseases. It acts by altering and improving the deteriorated blood. It seems to generate healthy granulations on cancerous ulcerated surfaces, and to promote rapid cicatrisation.

REVIEW OF BOOKS.

Lectures: Chiefly Clinical. By Thomas King Chambers, M.D., Physician to St. Mary's and the Lock Hospitals. Pp. 599. London: Churchill and Sons. 1864.

The present volume is substantially the same as the book which in two former editions was entitled by the author 'The Renewal of Life,' but this appellation was considered by the critics as of such an objectionable nature, that it has been discarded from the title-page. The fact is, that, without meaning any harm, Dr. Chambers had certainly given to the outside of his former book a "sensational" appearance, with which the contents by no means corresponded, for they consisted of a series of clinical remarks and lectures delivered during the course of hospital practice; and although the lecturer showed himself to be an independent thinker and prescriber, there was nothing quackish or extravagant in the doctrines inculcated or the practice pursued. The present book has a very modest appearance and a very brief and common-place title; and we congratulate the author both on the publication of the lectures in their existing form, and on his own convalescence from a most distressing illness.

The subjects discussed are very numerous, and are not arranged in any consecutive order. The leading idea which they illustrate (if they can be said to illustrate any at all) is, that disease is a diminution of vital power tending towards death, and that, therefore, all curative agency, by preventing this tendency and restoring the vital powers, is a "Renewal of Life." Expressed in the terms used by the author, there is no fault to be found with the idea, or with the manner in which it is worked out; for in no case can it be said that any erroneous treatment is insisted upon as a necessary corollary of crotchetty theories, or, indeed, that any views are advocated which might not have emanated from any other accomplished hospital physician, writing from the results of his experience.

The theoretical portions of the volume are comparatively few, the great bulk being made up of the record of cases which actually occurred, and which are frequently grouped together for the sake of analysis, or comparison. In the selection of

cases for clinical instruction, the author has purposely chosen those which are of most common occurrence, very properly considering that they are the most adapted for the guidance of the student, who will meet with them most frequently in his subsequent career; while the rare cases, sometimes exclusively chosen by clinical lecturers, will, perhaps, never present themselves to a medical man in ordinary practice. Thus we find that fever, pneumonia, rheumatism, hysteria, anæmia, consumption, and many other common diseases, form the text of many of the lectures; while others are devoted to what may often be considered as mere symptoms—as pain in the stomach, vomiting, costiveness, and the like. These are, however, just the subjects with which the student requires to be made familiarly acquainted, and which he is not taught in the systematic lectures delivered at the medical schools. We do not wish it to be implied that we condemn the teaching of medicine in a systematic manner—far from it; we think such teaching absolutely essential to the formation of accurate habits of thought and reflection, but inasmuch as diseases present themselves indiscriminately, and not systematically, to our notice, the clinical teacher is a necessary complement to the systematic professor of medicine. There is the same difference between Dr. Chambers' book and a treatise on the practice of Medicine as between a description of the fauna or flora of a particular country and a treatise on zoology and botany; but both books are very useful in their way.

Dr. Chambers is tied down to no school in his doctrines, and his practice is eclectic—that is to say, he accepts or rejects any given mode of treatment according as he finds it or thinks it beneficial or otherwise, and he changes his own opinions if he finds them no longer tenable. On many debatable points he offers what appears to be a candid and well-balanced judgment: blood-letting is considered useful in certain specified cases, notwithstanding the condemnation which has been lately passed upon it in certain quarters. Alcohol is pronounced to be neither a poison nor an elixir vitæ, but an agent powerful for good or for evil, as it may be judiciously or injudiciously employed. Mercury is commended in certain cases, but condemned in others. Among the peculiarities of Dr. Chambers' practice are the *jacket-poultice* in inflammation of the chest; the recommendation of *blanketing* in rheumatic fever; and the proscription of tartar emetic as a remedy in disease, in which latter particular we by no means coincide with him. Several years since we had the same opinion inculcated upon us by an eminent member of the Profession, but we have subsequently seen so much benefit follow from the judicious use of tartar emetic, especially in diseases of the respiratory organs, that we look upon it as a remedy of inestimable value.

CONTAGIOUS DISEASES BILL.

The following are the principal provisions of the Contagious Diseases Bill, as amended by the Select Committee:—

The Admiralty and the Secretary of State for War shall, on the passing of this Act, appoint a superior Medical officer of her Majesty's navy or army to be, during pleasure, Inspector of Hospitals certified under this Act, and may from time to time, on the death, resignation, or removal from office of any such inspector, appoint any such officer in his stead.

On the application of the authorities having the direction or management of any Hospital desiring that such Hospital should be certified under this Act, the Admiralty and the Secretary of State for War may direct the Inspector of Hospitals to examine and report to them on the condition of that Hospital, and on the regulations established for its direction and management.

If on such examination and report the Hospital appears to the Admiralty and the Secretary of State for War to be useful and efficient for the purposes of this Act, and is certified in writing to be so by the Admiralty and the Secretary of State for War, the same shall be deemed a certified Hospital for the purposes of this Act, and every such Hospital is in this Act referred to as a certified Hospital.

The Inspector shall, from time to time, visit and inspect every certified Hospital.

If on the report of the Inspector respecting any certified Hospital the Admiralty and the Secretary of State for War think proper to withdraw their certificate, that Hospital shall thereupon cease to be a certified Hospital for the purposes of this Act.

Where an information, in the form given in the second Schedule to this Act, or to the like effect, is laid before a Justice of the Peace by a superintendent or inspector of police or constabulary authorised to act in any place to which this Act applies, or by any Medical Practitioner duly registered as such, the justice may if he thinks fit, issue to the woman named in the information a notice in the form given in the same Schedule, or to the like effect.

A constable or other peace officer shall serve such notice on the woman to whom it is directed, by delivering the same to her personally, or by leaving the same with some person for her at her last or usual place of abode.

In either of the following cases, namely,—

'1. If the woman on whom such notice is served appears herself, or by some person on her behalf, at the time and place appointed in the notice, or at some other time and place appointed by adjournment;

'2.) If she does not so appear, and it is shown (on oath or affirmation to the justice present that the notice was served on her a reasonable time before the time appointed for her appearance, or that reasonable notice of such adjournment was given to her 'as the case may be): the justice present, on oath or affirmation being made before him substantiating the matter of the information to his satisfaction, may, if he thinks fit, order such woman to be taken to a certified Hospital for medical examination.

Such order shall be a sufficient warrant for any constable or peace officer to whom the order is delivered, to apprehend such woman, and to convey her with all practicable speed to the Hospital therein named, and for the authorities of the Hospital to cause her to be examined by some Medical officer of such Hospital, for the purpose of ascertaining whether or not she has a contagious disease, and in case, on such examination, it is ascertained that she has a contagious disease, then to detain her in the Hospital for twenty-four hours from the time of her being brought there.

Within the said period of twenty-four hours, the authorities of such Hospital shall cause a certificate, signed by the Medical officer who has made such examination, stating (if the fact be so) that on such examination it has been ascertained that such woman has a contagious disease, to be made out and laid before the justice by whom the order was made, or some other justice having the like jurisdiction; and thereupon such justice may, if he thinks fit, order the authorities of such Hospital to detain such woman in the Hospital for Medical treatment until discharged by such authorities, and such authorities shall detain her accordingly.

If any woman ordered as aforesaid to be taken to a certified Hospital for Medical examination refuses to submit to such examination, or if any woman ordered to be detained in a certified Hospital for Medical treatment refuses or wilfully neglects, while in the Hospital, to conform to the regulations thereof, or quits the Hospital without being discharged from the same as aforesaid, every such woman shall be guilty of an offence against this Act, and on summary conviction thereof before two or more Justices of the Peace shall be liable to imprisonment, in the case of a first offence, for any term not exceeding one month, and in the case of a second or any subsequent offence for any term not exceeding two months.

If any person, being the owner or occupier of any house, room, or place within the limits of any place to which this Act applies, or being a manager or assistant in the management thereof, induces or knowingly suffers any common prostitute having a contagious disease to resort to or be in such house, room, or place for the purpose of prostitution, every such person shall be guilty of an offence against this Act, and on summary conviction thereof before two or more

justices of the peace shall be liable to a penalty not exceeding ten pounds, or, at the discretion of the justices, to be imprisoned for any term not exceeding three months, with or without hard labour.

Provided that a conviction under this enactment shall not exempt the offender from any penal or other consequences to which he or she may be liable for keeping or being concerned in keeping a bawdy house or disorderly house, or for the nuisance thereby occasioned.

For the protection of persons acting in the execution of this Act,—all actions and prosecutions against any person for anything done in pursuance or execution or intended execution of this Act shall be laid and tried in the county where the fact was committed, and shall be commenced within three months after the fact committed, and not otherwise ; and notice in writing of such action and of the cause thereof shall be given to the defendant one month at least before the commencement of the action ; and in any such action the defendant may plead generally that the act complained of was done in pursuance or execution or intended execution of this Act, and give this Act and the special matter in evidence at any trial to be had thereupon ; and the plaintiff shall not recover in any such action if tender of sufficient amends is made before such action brought, or if a sufficient sum of money is paid into Court after such action brought, by or on behalf of the defendant ; and if a verdict passes for the defendant, or the plaintiff becomes non-suit, or discontinues any such action, after issue joined, or if upon demurrer or otherwise judgment is given against the plaintiff, the defendant shall recover his full costs as between attorney and client, and have the like remedy for the same as any defendant has by law in other cases ; and though a verdict is given for the plaintiff in any such action, such plaintiff shall not have costs against the defendant unless the judge before whom the trial is had certifies his approbation of the action and of the verdict.

This act shall continue in force for three years from the passing thereof, and no longer.

GENERAL CORRESPONDENCE.

GRIFFIN TESTIMONIAL FUND.

To the Editor of the Medical Circular.

SIR,—The following subscriptions have been further received on behalf of the above fund :—

ROBERT FOWLER, M.D.,

145 Bishopsgate st. Without, Treasurer and Hon. Sec.

July 27, 1864.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JUNE 1ST, 1864.

DR. OLDHAM, PRESIDENT.

The following gentlemen were elected Fellows of the Society :—Dr. Waller Balls ; Dr. A. Wahltuch, Manchester ; and Dr. W. B. Woodman, London Hospital.

Dr. HALL DAVIS showed a Craniotomy Forceps, whose blade fenestrated, of the form of a very elongated horse-shoe. It was composed of two parts, male and female ; the former serrated deeply, the serrations pointing backwards, and fitting into the depression in the female parts ; the lock like Naegelé's, and the handles fastening by a spring and rack at their extremities. This instrument he had tested practically, and found it answered admirably.

Dr. MEADOWS exhibited a Bandage, which he recommended in place of the jack-towel usually applied after labour. It was made of stout calico, shaped to the abdomen and hips, having one bone for extra support in front. When adjusted, it could be fastened firmly, either by bracket or laced like a corset, the advantages being, facility of application, combined with comfort and greater efficiency.

Drs. Routh, Oldham, Rogers, Graily Hewitt, and Meadows discussed some points connected with bandaging after labour.

Dr. AVELING, of Sheffield, read a paper

ON IMMEDIATE TRANSFUSION.

The author stated that transfusion had been performed now for two hundred years, and that for the first hundred and sixty years of that time the immediate method had been solely employed. He described the numerous forms of immediate apparatus hitherto used, and pointed out their faults and advantages. He also exhibited an instrument of his own, which consists of two small silver tubes to enter the recipient and emittent vessels, and of an india-rubber tube to connect them. This has in its centre a small elastic receptacle holding about two drachms, by compressing and relaxing which the blood is made to circulate through the tube, and the quantity passing is measured. He believed that there was less chance of coagulation by the immediate method, and that it had advantages over the mediate mode. The blood was not exposed to the air ; the operation was uninterrupted, and the closest imitation of nature.

Dr. CLEVELAND thought there would be danger of introducing air in the apparatus shown by Dr. Aveling, which was not transparent.

Dr. GRAILY HEWITT said the subject brought before the Society by Dr. Aveling was one of great importance, and one moreover in which he was individually much interested. In the course of last year he (Dr. Graily Hewitt) had brought the subject of transfusion before the profession in a paper read at the annual meeting of the British Medical Association held at Bristol, and he had exhibited at that meeting the apparatus for the performance of transfusion which he now begged to lay before the Obstetrical Society. He would remark that the great desideratum in an apparatus for transfusion, adapted for use in obstetric emergencies, was a simple, certain, and ready mens of conveying the blood. The instrument which he had contrived fulfilled, he believed, these indications ; and he had had an opportunity of using this instrument only a short time since in the case of a poor woman dying from loss of blood connected with placenta prævia. The instrument acted admirably, and by its means he was enabled to transfuse two successive portions of blood. The operation was unfortunately delayed, as it proved, a little too long, and the patient failed to derive benefit from the operation ; but the experience afforded by the case was such as to justify him in expecting the best possible results from its use in similar emergencies. The apparatus devised by Dr. Aveling, which in principle, he believed, resembled one that had been recommended by Dr. Richardson, was, he considered, objectionable for a variety of reasons. The want of transparency prevented the observer ascertaining what was going on in the tube ; it was not easy to connect, off-hand, the tube with the vein of the individual supplying the blood ; and, further, it would be found very objectionable to bring the individual supplying the blood into close proximity with the individual dying from loss of blood. The person supplying the blood was often, in obstetric practice, the husband of the patient ; and, unless under very exceptional circumstances, the nerve and fortitude of the individual in question would be likely so to break down as to interfere with the carrying on of the operation. For these reasons, therefore, he believed that, however ingeniously contrived, the "immediate" method could not become a practical operation. The instrument he (Dr. Graily Hewitt) had employed—constructed for him by Messrs. Whicker and Blaise—was a two-ounce glass cylinder, fitted at one end with a piston and rod, and at the other adapted to the tube entering the vein of the patient. The blood was received into the syringe itself, the piston being

removed for this purpose, and the blood was then injected. The peculiarity of the instrument was that the blood was received directly into the syringe, without the necessity for a funnel or other apparatus; and the exposure of the blood to the air and to foreign objects—which hastened to coagulation—was thus reduced to a minimum. The operation of transfusion required forethought and arrangement, and accurate appreciation of the difficulties surrounding its performance. These difficulties he had endeavoured to point out and to obviate, in the paper to which he had already alluded.

Dr. EASTLAKE was able to confirm Dr. Graily Hewitt's statement as to the applicability and value of this instrument, having assisted Dr. Hewitt at the operation in question. It would have been impossible in this case to have brought the husband, who supplied the blood, to the bedside. His nervousness and agitation under such circumstances would probably have prevented the performance of the operation.

Dr. BRAXTON HICKS hoped he should be able some day to bring before the Society a plan which he had employed with success in the lower animals, and also in a case of hæmorrhage in a lady. The principle of its action was to prevent fibrillation, thereby doing away with the greatest difficulty attending the operation.

Dr. AVELING, in reply, would remind the Society that the operation of transfusion had been successfully performed by the simplest means—such as quills; and he differed from Dr. Graily Hewitt in his estimate of the difficulties of the operation.

Dr. GREENHALGH read a paper on Placenta Prævia, the discussion upon which was adjourned to next meeting.

An abstract of this paper will appear in the report of the next meeting.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 28.

Mr. PARTRIDGE, President.

(Continued from page 65.)

Mr. J. A. KINGDON read a paper on

THE CAUSES OF HERNIA.

The object of the paper was to call in question the accuracy of the prevailing opinions concerning the causes of hernia. Instead of its being due almost entirely to mechanical causes, as most writers since the time of Scarpa have held, the author endeavoured to prove that hernia was the result of an abnormal condition of the peritoneum in its entirety, either from congenital malformation or inherent disposition to be relaxed. Without disputing the majority of the arguments that favoured the mechanical theory, the author attempted to show that mechanical causes could not operate without antecedent derangement of the peritoneum. So long as the mesenteries remained unrelaxed, in healthy bone, and with their normal attachments, the author held that hernia not only did not, but could not, occur, and that there was no disposable force that could stretch the mesenteries and dislodge the viscera. But when, from congenital defect or subsequent derangement, the mesenteries allowed the intestines to descend in the cavity of the abdomen below their proper sphere, then mechanical causes could act—then the arguments of those who advocated the mechanical theory would apply; protrusion would then be due to loss of equilibrium between the muscular parietes and the rings, but not till then. The author further attempted to show that hernia was fundamentally an affection of the peritoneum generally, by pointing out that the condition of the parietal layer determined the kind of hernia—*i.e.*, the aperture through which it escaped. The facts and arguments in support of these views were set forth in the paper.

A paper, by Dr. WILSON FOX, was read

ON THE ORIGIN, STRUCTURE, AND MODE OF DEVELOPMENT OF THE MULTILOCULAR CYSTS OF THE OVARIES.

The first division of the paper consists of a *résumé* of the views hitherto held with regard to the origin of these cysts. The author considers that the opinions hitherto expressed on this point may be divided into two chief classes. 1. Those which attribute the cysts of the ovary either to morbidly affected Graafian vesicles, or to secondary formations of these structures. 2. Those which ascribe the multilocular forms to a morbic process arising in the stroma of the ovary, independently of the Graafian vesicles. Under the second category there is a great variety and discrepancy of opinions. With regard to the former, it has long been doubted whether the number of the Graafian follicles normally existing in the ovary is sufficient to account for the whole of the cysts sometimes found in these tumours; while the proof of any fresh formation of Graafian vesicles taking place in the adult has hitherto been of a very dubious kind, nor has any account been furnished of the mode in which secondary cyst formations proceed from them. The author has studied these conditions in fifteen of the so-called "colloid cysts" of the ovary, for the opportunities of examining most of which he has been indebted to the kindness of Mr. Spencer Wells. He believes that all primary cysts of the ovary originate in the destruction of the ovum and subsequent accumulations of fluid in the follicle, the membrana granulosa acting as a secreting structure. From these cysts secondary cysts may originate in various ways, all of which, however, may be referred to one common type. Class A.—Cysts give off long tubular processes, lined by an epithelium similar to that of the cyst whence they spring; one cyst may give off two or three such processes at various parts of its circumference. These undergo constrictions in their course, and thus form secondary cysts. These processes and the cysts from which they spring are most easily found in the more dense parts of the stroma. Class B.—Thin-walled cysts give off diverticula analogous to those by which the lungs, the thyroid, and some other glandular organs, both of the gusto-pulmonary and genito-urinary system, originate in the embryo. These diverticula, which open by a narrow neck into the cavity of the parent cysts, expand as large pouches on its external surface, protruding into other and adjacent cysts. The neck may either expand into a large opening or may become constricted, in which latter case the original communication is destroyed. One cyst may in this manner give off numerous diverticula. These varieties (A and B) usually co-exist in different parts of the same tumour. They were found by the author in three out of the fifteen tumours examined by him. They give rise to very compound structures, but not to the dense masses to which the names of "alveolar degeneration," "cystoid disease," and "adenoid tumours" of the ovary have been given. This variety (or Class C) results from the formation, on the inner surface of the cyst-wall of a series of tubular glands, analogous to those of the uterus, or the crypts of Lieberkühn, or the glands of the stomach. They are formed by the (1) epithelium lining, the parent cyst becoming stratified, and in its superficial layers assuming a columnar character. (2). Into this stratified epithelium, papillæ formed of connective tissue spring from the stroma of the ovary, in each of which a loop of vessels is formed. A series of densely-clustered villi is thus produced, which are converted into tubular glands by the growth upwards around these bases of the stroma of the ovary. The glands may become compound at their bases by secondary villi arising in them. They may be converted into simple cysts by the closure of their orifices; but more commonly the upward growth of the stroma surpasses that of the villi in which their summits end, and the glands become completely shut off and enclosed in the stroma, forming groups of a very compound form, of tubular structure, lined by a secreting epithelium embedded in the wall of the parent cyst. When distended by further secretion they form the smaller and larger multilocular cysts scattered on the inner wall of the parent cyst. Other modes of cyst-formation resulting in dense cystoid masses were traced by the author to these structures. Class D refers to the cyst found in the cauliflower papillary or dendritic growths which spring from the interior of parent cysts. These growths originate in a number of delicate papillæ growing from a common basis,

and uniting to form larger masses. They consist of a delicate stroma, derived from that of a parent cyst-wall, a loop of vessels, and a covering of epithelium. The irregularity of their growth causes spaces to be enclosed by them, lined by a secreting epithelium, and which, when completely shut off, become cysts. Various illustrations were given of this process. The author considers that in no case are the secondary cysts in the cauliflower growths of the ovary derived from single epithelium cells. The author then referred to the observations of Drs. Pflüger and Billroth on the origin of the Graafian follicles from tubular structures found in the embryonic condition of the ovary; and though not fully able to corroborate all Dr. Pflüger's views from his own observations, he has convinced himself that the Graafian follicles originate in tubular structures. He regards these cysts as resulting from a renewal in the adult of the early mode of development of the Graafian vesicle with various morbid aberration from the type of embryonic growth, and thinks they must therefore be placed in the same category with other cystic tumours growing in structures having tubular glands and ducts, especially with those of the mamma, testicle, the thyroid gland. He regards the cysts mentioned under class D as presenting essentially the same type, inasmuch as the large papillary and cauliflower masses can only be regarded, similarly to the Haversian fringes of synovial membranes, as everted glandular structures. He has not had any opportunities of examining any multilocular cysts of the ovary containing dermoid structures; but, inasmuch as these have been shown to contain both normal hair follicles and sebaceous and sudoriparous glands—all of which structures are the frequent seat of cyst formations—he believes that they will be proved to follow the same laws of growth as the colloid cysts. The author, from chemical examinations of the fluid contents of the cysts, has been led to regard the so-called colloid matter found in them, as the result of alterations depending on the varying conditions of pressure under which they are secreted from the inner surface; and he believes that this matter cannot be considered as the result of any special form of degeneration of the tissue of the ovary. The method which the author has pursued in studying the development of the cysts of the Clauses A C D has been to make sections in the recent state with a Valentin's knife through various parts of the stroma. The glands of Class C are best displayed by sections made vertically to the inner surface of the cyst-wall. Observations on Classes C and D are much facilitated by hardening the tissues in chromic acid solution of two per cent., and subsequently treating sections made by a sharp razor with liquor of soda and glycerine.

BIRTH.

Paterson.—On the 19th ult., at Balbeggie, Perthshire, the wife of George K. H. Paterson, L.R.C.P. & L.R.C.S.Ed., of a son.

DEATHS.

Abraham.—On the 16th inst., at Marsden Villa, Haverstock hill, Thos. Abraham, M.D., late of New Broad street, aged 56.

Ammer.—On the 9th inst., at Presbury, Hungary, Nikolous Ammer, M.D., aged 56.

Barnes.—On the 18th inst., at Rupert road, Upper Holloway, John Barnes, M.D., formerly of Tavistock place, aged 63.

Don.—On the 18th inst., at Bearchill, Brechin, Forfarshire, N.B., James Don, M.D., retired Surgeon-General, Bombay.

Fell.—On the 18th inst., at Ambleside, Westmoreland, W. Fell, M.R.C.S.E., aged 62.

Forrester.—On the 30th ult., suddenly, on board the Steamship "Nubia," in the Red Sea, on the homeward passage from India, Wm. Forrester, Surgeon Madras Army, aged 45.

Jones.—On the 7th inst., T. R. Jones, M.D., of Aberystwith, aged 35.

The Inverness District Lunatic Asylum has been recently opened. Accommodation is provided for 350 patients. The hospitals and infirmaries for the male and female patients are detached buildings, each hospital being fitted up for forty inmates.

THE INDIAN MEDICAL SERVICE BILL.

The following is the division list on the occasion when the above Bill was rejected on its Third Reading.

Ayes.	*Noes.*
Ayrton, Acton Smee.	Astell, John Harvey.
Baring, Rt. Hon. Sir F. T., (Portsmouth).	Aytoun, Roger Sinclair.
Baring, Thomas G. (Penryn).	Beecroft, George Skirrow.
Bouverie Rt. Hon. E. P. (Kilmarnock).	Bramston, Thomas William.
Bouverie, Hon. P. Pleydell (Berks).	Briscoe, John Ivatt.
Bruce, Rt. Hon. Henry Austin (Merioneth).	Brooks, Robert.
Bury, Viscount.	Burrell, Sir Percy.
Cardwell, Rt. Hon. Edward.	Butler-Johnstone, Hon. A. (Canterbury).
Childers, H. Culling Eardley.	Cecil, Lord Robert.
Collier, Sir Robert Porret.	Clay, James.
Cowper, Rt. Hon. William F.	Clifton, Sir Robert Juckes.
Craufurd, Edward Hy. J. (Ayr).	Colebrooke, Sir Thos. Edward.
Crawford, Robert W. (London).	Cox, William.
Doulton, Frederic.	Duff, Mount. Elph. Grant (Elgin).
Fermoy, Lord.	Farquhar, Sir Minto.
Gibson, Rt. Hon. Thos. Milner.	FitzGerald, William R. S.
Gilpin, Chas. (Northampton).	Fleming, Thomas Willis.
Gladstone, Rt. Hon. William.	French, Colonel.
Goschen, George Joachim.	Gard, Richard Sommers.
Gower, Hon. F. Leveson (Bodminster).	Greene, John.
Grey, Rt. Hon. Sir Geo. (Morpeth).	Hadfield, George.
Headlam, Rt. Hon. Thomas Emerson.	Hamilton, Major (Linlithgow).
Howard, Hon. Charles W. G. (Cumberland).	Hay, Sir John C. Dalrymple.
Hutt, Rt. Hon. William.	Howes, Edward.

MEDICAL NEWS.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 26th ult.:—Charles Edward Blair, Wandsworth; Alex. Hampton Brewer, Victoria, Monmouthshire; Thomas Collier, Bridgend, Glamorganshire; George Covey, Basingstoke; John Hamilton Craigie, Finsbury square; Richard Rothwell Daglish, Wigan; Thomas Henry Whitehouse Davies, Stroud; Henry James Divelly, Wandsworth; John Challen Duke, Leominster, Sussex; John Moore Fisher, Hull; George Gill, Liverpool; John Hankinson Gornall, Liverpool; John Hedley, Newcastle; George Henry Hills, Old Kent road; Thomas Laffan, Dublin; Augustus Square May, Plymouth; James More, Rothwell,

Northamptonshire; Thomas Henry Morris, Spalding; Walter Hugo Reed, Tiverton, Devon; William Matthew Renton, Shotley Bridge; John Coryton Roberts, Peckham; George Henry Savage, Brighton; Frederick Turner, Buxton; William Foster Vise, Spalding; John Hargreave Wraith, L.S.A., Over Darwen.

The following gentlemen were admitted Members on the 27th ult.:—William Bailey, L.S.A., Tipton, Staffordshire; Henry Barnes, Wigton, Cumberland; Joseph Edward Collingwood, Corby, Lincolnshire; Thomas Fairbank, Islington; Ernest Last Fyson, Exning, near Newmarket; Richard Carter Goddard, Stockport; William Henry Harding, Wormley, Herts.; Henry Cripps Lawrence, Surbiton; Paulin Martin, L.S.A., Abingdon; Lewis Wayne Morgan, Hafod, Glamorganshire; Thomas Renny Strachan Nivison, Edinburgh; David Renton, M.D., Madeira; James Francis Hamilton Richardson, Down, Kent; Thomas Edward Roberts, Gibraltar; Charles Edward Heron Rogers, Westmeon, Hants; Joseph Hiram Shearwood, Spilsby, Lincolnshire; Ebenezer Fulham Turner, Upper Clapton; Alfred Edward Wilmot, Ryde, Isle of Wight; Stephenson Moreton Wightman Wilson, Mowsley, Leicestershire; William Thomas Hurd Wood, Notting hill; Charles James Wright, Wakefield.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 21st inst.:—Roderick William Henderson, Lower Halliford, Middlesex; Richard Jackson, Birmingham; William Melville Knipe, Guy's Hospital; William Cubitt Lucey, Bermondsey; Philip Brookes Mason, Burton-on-Trent; William Fred. Ruttledge, London Hospital; William Yates, Richmond green.

The following gentlemen also on the same day passed their first examination:—William Le Gros Denziloe, St. Mary's Hospital; William Griffith Jones, Middlesex Hospital; William John Land, St. Mary's Hospital; Thomas Charles Murphy, University College; James Copland Worthington, Middlesex Hospital.

Mr. Fope Hennessy.—The member for King's County, who rendered such good service to the Profession by leading the opposition to the India Medical Service Bill, has already on more than one occasion shown his interest in the Medical profession. It will be remembered that it was his amendment on the Irish Registration Bill that substituted Medical practitioners for the constabulary as registrars. We believe that Mr. Hennessy was educated for the Profession of Medicine, and passed through the classes with considerable distinction.—'Lancet.'

Arrival of Dr. Livingstone.—This distinguished African traveller arrived by the Paris express train at the Charing cross Railway Station on Saturday evening last.

Punishment for Assaulting a Surgeon.—A private of the 1st battalion of the 19th Regiment, stationed at Jullundur in the East Indies, has been sentenced to penal servitude for life for striking an assistant-surgeon in his cell when a prisoner. The sentence has been confirmed by Sir Hugh Rose.

The Wounded Guardsman at Wimbledon and the Volunteer Surgeons.—On Thursday, the 21st, at the camp at Wimbledon, a guardsman, named Thomas Cooper, employed as marker at the butts, unluckily exposed himself and received a ball, which entered an inch and a-half below the angle of the left scapula, passed through the lung, and without perforating, lodged between the cartilages of the third and fourth ribs, where it was wedged in, and could be felt about two inches obliquely above and internal to the left nipple. The man had all the symptoms of wounded lung: collapse, difficult breathing, intense pain, no great bleeding outwardly, some cough, and blood expectorated in frothy fluid mouthfuls. He was brought under the care of Dr. Westmacott, of the London Scottish Volunteers—formerly Surgeon to the New York Artillery, and well-known as an accomplished Surgeon, and as adding the artistic talents of his family to his Professional acquirements—to that gentleman's own tent, where he was soon after seen by Dr. Buzzard, of the Queen's (an old Crimean man); Dr. Shepherd, of the Victorias; Dean, of the Middlesex; Dr. Halley, of the London Scottish; and Staff-Surgeon Guinness of the Guards, and others. When Dr. Westmacott had ascertained the facts as above stated, he and his colleagues decided that it would be better to leave the case without any attempt to extract the ball, although they had at hand, with commendable forethought, every instrument for the purpose that modern ingenuity could devise. Emphysema was beginning over the left clavicle and extending to the right. The exploration was made under the use of chloroform, and in view of the apparent hopelessness of the patient, it was continued from time to time to ease his sufferings. Curtis's chlorodyne also was given with good effect, iced water with brandy in abundance was administered, and the patient got through the night with great distress. The next day vomiting came on, but not of blood; on Saturday retention of urine; a few mouthfuls of dark blood were also expectorated. Surgeon Trotter, Mr. Prescott Hewett, and Surgeon-Major Wyatt were also called in consultation, and in spite of the unpromising aspect of the case, the poor fellow is likely to do well. It is but bare justice to the Volunteer Surgeons, and it ought to be a source of satisfaction to the volunteers and their friends, to state that the former have many experienced Army Surgeons amongst them, and are capable of attending efficiently to every casualty that may occur. They were amply occupied at this review with lesser injuries to the eyes arising from the detonation of Government caps, bruises of the fingers, &c. One death is reported from sunstroke.—'Medical Times and Gazette.'

Dinner of the Apothecaries' Society.—The Annual Herbarizing Dinner of the members of the London Society of Apothecaries was held at the Castle Hotel, at Richmond, on Friday last. This dinner, the cost of which is defrayed by private arrangement among the members themselves, was originally instituted for the purpose of encouraging and promoting the science of botany, by the collection of the indigenous plants growing around the metropolis, but the increase of buildings, and the consequent destruction of the suburban native Flora, have frustrated this design, and the dinner is now perpetuated only for the purpose of maintaining a social feeling among the members of the company, the master and wardens of which usually invite the chiefs of the different Medical and Surgical Departments to meet them on the occasion. Mr. Henry Combe, the Master, occupied the chair, and was supported by Dr. Gibson, the Director-General of the Army Medical Department, Dr. Bryson, the Director-General of the Navy Medical Department, and several representatives of the Royal Colleges of Physicians and Surgeons, among whom were Dr. West, Dr. Basham, Dr. Sibson, Dr. Fraser, Mr. Campbell de Morgan, Mr. Barnard Holt, Mr. Nunn, &c. Dr. Gibson, in responding to the toast of the Army, declared that the Medical Service of the Army was in a state of general efficiency, but he made very little allusion to the questions now pending between the Army Medical Service and the Government. The arrangements made by the stewards in providing the dinner, gave general satisfaction.

Bravery of Army Surgeons in New Zealand.—Sir Duncan Cameron, the General Commanding in New Zealand, in a despatch dated Tauranga, May 3rd, 1864, thus refers to the courage displayed by three medical officers during the recent engagement with the Maories:—"I am much indebted to all the officers commanding and heads of departments for the zeal and activity with which they discharged their respective duties; but I must particularly mention the valuable services of Deputy Inspector-General Mouat, Surgeon M'Kinnon, 57th Regiment, and Assistant Surgeon Manley, Royal Artillery, who fearlessly exposed themselves to fire in attending to the wounded, the greater part of whom fell close to the enemy's work."

St. Mary's Hospital.—The students of St. Mary's Hospital have recently presented to Mr. G. G. Gascoyen, Assistant-Surgeon and Lecturer on Anatomy at the Hospital and School, a service of plate, inscribed. The testimonial was presented by Mr. Raynes, House-Surgeon, in the board-room, with an appropriate address expres-

sive of the feelings of esteem with which the past and present students regarded the services of Mr. Gascoyen during his tenure of the office of Dean of the School and as a teacher of Anatomy.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, AUGUST 3.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, Caledonian road, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, AUGUST 4.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, AUGUST 5.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, AUGUST 6.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

MONDAY, AUGUST 8.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, AUGUST 9.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

THE OBSTETRICAL SOCIETY OF LONDON.—The report has been received.

DR. ROBERT FOWLER.—The list is inserted.

MR. G. K. PATERSON.—The announcement is inserted.

STUDENS.—The examinations at the College of Surgeons of England are no longer held weekly, but on such occasions as are determined by the authorities. The first examination is always practical, and is conducted upon the dissected subject.

MR. T. H.—The Life Assurance Office in question is a highly respectable one, and the proposed amalgamation consists of the absorption of the other office, which will cease to exist.

DR. TUCKER sends us the following receipt for Mont D'Or water, taken from Beasly's 'General Receipt Book':—

℞ Bicarb. sodæ, gr. 70,
Sulph. ferri, gr. ⅔,
Mur. sodæ, gr. 12,
Sulph. sodæ, gr. ¼,
Mur. calcis, gr. iv.,
Mur. magnesiæ, gr. ij.,
Aquæ aëratæ, lb. j. [See page 199.]

Is this correct and genuine?

SUBSCRIPTIONS FOR THE LATE MR. BULL'S FAMILY.

To the Editor of the Medical Circular.

SIR,—The Rev. H. Bromfield acknowledges with thanks the receipt of 5s. in stamps for Mrs. Bull from C.F.G. and J.M.

Blockley Vicarage, July 29, 1864.

MR. B. S.—Podophyllin in the resin of the *Podophyllum peltatum*, of the natural order of Podophyllaceæ. It is very liable to cause griping, and should therefore be combined with hyoscyamus, or extract of Indian hemp.

DR. R. C.—We have noticed the matter among our leading articles.

QUÆSO.—We have heard of the subject alluded to, but do not deem it of sufficient importance to lay before our readers. The conduct of the principal person is quite in accordance with what we should have anticipated.

University College Medical Dinner, WILLIAM CADGE, Esq., F.R.C.S., in the Chair, will be held on Thursday, NOVEMBER 3rd.
Further particulars will be announced by Advertisement.
J. RUSSELL REYNOLDS, M.D., EMANUEL BAKER, } Hon. Secs.

The Medical Baths and Fumigations. 40 GREAT MARLBOROUGH STREET, REGENT STREET, W. Established by Dr. JONATHAN GREEN, 1822.
Chlorine, Sulphur, Mercurial, Fumigations, Hot and Cold Water, Hot Air and Vapour, Nitro-Muriatic Acid, Alkaline, Chalybeate, Iodine, Artificial Barèges, Harrogate, and other Baths, constantly ready, or prepared to order.
These baths are highly esteemed, and have been mainly supported now for upwards of forty years, by the goodwill and recommendation of the Profession, as an additional, very effective, and agreeable remedy in chronic disease where internal medicines are inadmissible, or have altogether failed. In effect. Imitations having arisen, be particular in the address.

Vapour Bath Apparatus. — Mr. CHANDLER, Anatomical Mechanician, begs to announce that he has been appointed sole Agent, in England, for the Sale and Hire of Dr. LEFEBVRE'S PATENT PORTABLE VAPOUR BATHS. It has been pronounced by the Profession to be the most perfect and effectual means of introducing through the pores of the skin into the body any medical preparation. To be seen in operation at the London Establishment, 66 Berners street, Oxford street.—Inspection invited.

Leeches, Turkey Sponge, and all Kinds of Medical Herbs. Best and Cheapest at H. POTTER'S DEPOT, 65 FARRINGDON STREET, LONDON, E.C.
His New Priced Catalogue (sent to any address on application. Established 1812.

Liquor Carbonis Detergens, or Con- CENTRATED ALCOHOLIC SOLUTION OF THE ACTIVE PRINCIPLES OF COAL TAR.—A new remedy in Cutaneous affections, &c., presenting in an elegant and effective form the several virtues of the Tar, which are held in solution by the Alcohol, and thus rendered applicable to all the purposes of Hygiene, Medicine, and Natural History. As a dressing for putrid sores, where a disinfectant is at the same time desirable, the Emulsion, formed of any required strength by the addition of water, is most readily exhibited, mere agitation producing immediately perfect combination.
Prepared at the Laboratory of WRIGHT, FRANCIS, and CO., Wholesale Druggists, 11, Old Fish street, London, E.C.: and may be obtained through any Chemist.—(Name and Label entered at Stationer's Hall.)

Aloina.—T. and H. Smith, the Dis- coverers of this,
THE CRYSTALLINE PURGATIVE PRINCIPLE OF ALOES,
(vide 'Edinburgh Monthly Journal of Medical Science' for Feb. 1851,) continue to prepare and supply it. They have the gratification of knowing that the most eminent of the Profession prescribe it, to the exclusion alto gether of the various kinds of aloes.
Orders executed direct, or through any Drug House, by T. & H. SMITH and CO., 69 Coleman-street, City, London, and 21 Duke street, Edinburgh

Lichen Islandicus, or Iceland Moss COCOA.
Strongly recommended by the Faculty.
See Testimonials of Dr. Hassall, Dr. Normandy, with others. To be had everywhere, at 1s. 4d. per lb.
Manufactured by
DUNNAND HEWITT, LONDON.

Medical Fixture and Glass Ware- HOUSE.—W. HAY and SONS, 25 Little Queen street, Lincoln's inn fields, beg to inform the Profession that they Fit-up every description of Medical Shops and Surgeries, and have in Stock a large assortment of New and Second-hand Drawers, Counters, Desks, Dispensing Screens, Bottles, Jars, and every requisite for the above.—A large Assortment of Medical Lamps.

J. Clarke (late Thompson), Surgical Instrument Maker, Cutler, Truss and Bandage Maker, 225 Piccadilly, near Regent's Circus, W.

T. Weedon, Surgical Instrument MAKER and CUTLER, 41 Hart street Bloomsbury square (near the Church), W.C., London, Surgical Instruments, &c., ground and repaired. Table Cutlery, Instruments for Microscopic Dissection, Trusses, Elastic Stockings, Knee-caps, and other Bandages, Dental Instruments made to any pattern.

Surgical Instruments.—Arnold and SONS continue to supply Instruments of the best workmanship at moderate prices, manufactured on the premises under their own superintendence.
ARNOLD & SONS, 35 and 36 West Smithfield, E.C. Established 1819.

J. Millikin, Surgical Instrument Maker to Guy's and St. Thomas's Hospitals, 12 SOUTHWARK STREET, BOROUGH, from St. Thomas's street.
J. Millikin has no connection whatever with other establishments using his name.

BARTH'S OXYGEN WATER

HOLDS FREE OXYGEN IN SOLUTION,

gently stimulates the functional action of the stomach and secretory organs, and is a very pure useful beverage. WENTWORTH SCOTT'S Analysis gives as contents of a bottle—"Nearly half of an imperial pint of distilled water, and about 13·5 cubic inches, or 4·6 grains of gaseous oxygen; equivalent to that contained in 21·4 grains of chlorate of potash."—4s. per dozen.

OXYGENATED WATER COMPANY (LIMITED), 36 LONG ACRE.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

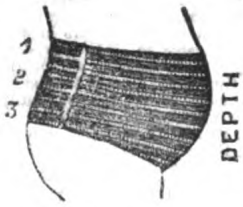
where there is the LARGEST STOCK IN LONDON, is Mr. WILLIAM LAWLEY'S, 78 FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms Elliott, and other eminent makers.—Catalogues forwarded on receipt of Stamp.

BLOCKEY'S LONDON STOUT

NOURISHING LONDON STOUT

DR. HASSALL'S REPORT:—"I have carefully analyzed Blockey's well-known Stout, as obtained from 21 Duke street, St. James's, and find it to be a genuine, most wholesome, and highly nourishing beverage, less heavy, and consequently more digestible than London Stout in general.—Signed, ARTHUR HILL HASSALL, M.D London, Analyst of 'The Lancet' Sanitary Commission." Casks of 4½, 6, 9, and 18 gallons, at 1s. 8d. per gallon; 3s. per dozen pints; 5s. quarts.



RAGGETT, late Blockey, 21 Duke st., St. James's. Established 100 years.

Pulvis Jacobi ver, Newbery

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

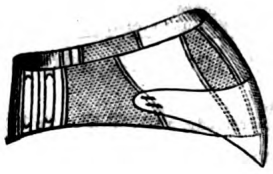
Prices for Dispensing—1 oz., 9s.; ½ oz., 3s. 4d.

MR. P. BOURJEAURD'S REGISTERED SPIRAL ELASTIC

BANDAGES, to be obtained only at No. 11 DAVIES STREET, BERKELEY SQUARE, W., and No. 49 RUE DES BEAUX-ARTS, PARIS.

Mr PHILIP BOURJEAURD, in submitting the accompanying diagrams, presents his best thanks to those Gentlemen who have, for some years past, prescribed his appliances in cases indicating their necessity, and begs respectively to assure others, who have not used them in their practice, that they will find them a most valuable assistance in most cases indicating their necessity of compression or support. The inventions consist of Abdominal Supporters, Hernia Apparatus, Ankle, Knee, and other Bandages, with various other Appliances, that the élite of the Profession have pronounced to be most ingenious.

N.B.—No. 49 DAVIES STREET, BERKELEY SQUARE, W., near Mivart's Hotel. The establishment is strictly private, not having any show of Bandages in the window. A highly-respectable married female to wait upon Ladies, who may insure her attendance in Davies street, or at their own establishments, by favouring Mr Bourjeaurd with instructions according to their own preference.—Poor Patients are supplied at a reduction of thirty per cent. lower than the imitations.



AT HOME FROM TEN TILL SIX.

J. & E. BRADSHAW,

LATE

SHOOLBRED AND BRADSHAW,

34 JERMYN STREET,

Beg to call attention to the various improvements in Patent ELASTIC STOCKINGS, BELT, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera and the cure of Rheumatism, Lumbago, &c.

*** **Every description of INDIA-RUBBER BANDAGE, vulcanised on the newest principle.**

Directions for Measurement sent by post.

N.B.—A Liberal Discount to the Profession.—A Female to attend on Ladies.

H. Silverlock's Medical Label Warehouse, Letter-Press, Copper Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctors Commons, London, E.C.

DISPENSING LABELS, for the use of Surgeons.

YELLOW, GREEN, AND GOLD LABELS, for Drug Bottles, Drawers, &c.

SET OF YELLOW OR GREEN LABELS, for Surgeries, 10s. 6d.

LABEL DRAWERS, for Dispensing Labels of various sizes.

A Set of Labels in accordance with the 'BRITISH PHARMACOPŒIA' now ready.

Pepsine and Pepsine Wine.—Boudault begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Chemist in Ordinary to the Queen and H.R.H. the Prince of Wales, 227 Oxford street, London, to whom all applications respecting it must be addressed.

Third Edition, with Further Remarks by Dr. CORVISART, Physician to the Emperor of the French, edited by W. S. SQUIRE, Ph. D.; published by J. Churchill, London; may be also had of the Author, 277 Oxford street, price Sixpence.

Flour — (Essex) — Warranted free from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs.), 9s. 0d. Households (recommended for bread-making), 7s. 8d.; Seconds, 7s. 0d.; Wheat Meal for brown bread, 7s. 0d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

Kamptulicon, Floor-cloth. — The attention of the Medical Profession is requested to be given to the many advantages of this article as a floor covering, for the Wards of HOSPITALS, Surgeries, Nurseries, &c. It is non-absorbent, quiet, and warm to the tread, will not hold dust, is very easily and quickly cleaned and will stand any amount of hard wear. It has already been adopted in several hospitals.

GOUGH and BOYCE, 76 CANNON STREET WEST
Original Patentees and Manufacturers.
Forwarded to all parts of the Country.

Whicker and Blaise, late Savigny and Co., Wholesale and Retail Cutlers and Surgeons' Instrument Makers, No. 67 St. James's street, from Pallmall and King street, London, and at their Manufactory, Young's place, Wood street, Westminster.

Microscopic Glass.—Thin Glass for Mounting Objects, in squares or circles. Slides 3 in. by one in., and Cells of every kind, supplied Wholesale and Retail, by

CLAUDET and HOUGHTON, 89 High Holborn London.
N.B.—Aquariums, Fern Cases, and Glass Shades.

Bennett's Watches, 65 & 64 Cheapside, in gold and silver, in great variety, of every construction and price, from 5 to 60 Guineas. Every Watch skilfully examined, and its correct performance is guaranteed. Free and safe by post.

Money Orders to JOHN BENNETT, Watch Manufactory,
65 and 64 Cheapside, and 6 Cornhill, E.C.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

By J. Lumley Earle, M.D.,
Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 68.)

The Causes, Diagnosis, and Treatment.

I have seen two instances of hour-glass contraction, but as there was no flooding in either, I shall not mention the particulars. The placenta in both cases was shut up and firmly compressed in a small compartment of the uterus, so that the uterine sinuses were very efficiently plugged. The following case is an example of hæmorrhage, resulting from retention of the placenta by a firm contraction of the os uteri. The patient was attended in her fourth labour by a pupil of the Dispensary. He sent for me in consequence of retention of the placenta, and flooding, which he was not able to control. The child had been born three-quarters of an hour when I arrived. On external examination, the uterus was felt unusually large, and was tender to the touch. Internally, the insertion of the cord could be readily made out just within the os, which was so contracted, as barely to allow two fingers to pass through. The pupil stated that he had tried firm traction, but with no effect, except that of aggravating the discharge. If the case had been in my own hands from the commencement, I should most likely have first tried drawing the placenta through by traction on the cord ; but the patient had lost a great deal of blood, and from the size of the uterus I concluded there were clots in utero, besides the afterbirth. Therefore, I thought it advisable to introduce my hand. The os was gradually dilated, and the hand passed through. The placenta was lying loose in the lower part of the uterus, and above it was a mass of clots. On their removal, the uterus contracted firmly, the tenderness disappeared, and the flooding ceased.

Inversion of the Uterus.—This dangerous accident fortunately happens very rarely. It sometimes occurs spontaneously, but is more commonly due to mismanagement in the delivery of the placenta. It is generally attributed to premature traction on the cord, while the placenta is still attached. There are two instances on record in which, apparently, strong pressure externally inverted the uterus. Mr Ingleby traced its occurrence on two occasions to unskilfulness in separating the adherent placenta. The cord being unusually short may also produce it.

Diagnosis.—Immediately on the occurrence of inversion dangerous constitutional symptoms exhibit themselves, the result of nervous shock and loss of blood—such as syncope, nausea or vomiting, and a quick and feeble pulse. The face is pale, and covered with cold clammy moisture. The patient also suffers from constant and violent forcing pain in the hypogastric and pelvic regions. The symptoms of sudden collapse, of themselves would not be sufficient to indicate the occurrence of inversion of the uterus, for they might be due to other causes, as rupture of the uterus or vagina closely preceding the birth of the child, an overwhelming loss of blood, simple but severe nervous shock consequent on the exhaustion and sufferings of labour, the existence of a large polypus of the uterus hanging in the vagina, or an immense thrombus of the vulva. The nature of the accident is very soon cleared up on making an external and internal examination of the uterus. Generally, the uterus cannot be felt at all in the supra-pubic region. When the inversion is only partial, a portion of the uterus may be felt, as in an instance which came under Mr. Ingleby's observation. In all cases, however, the roundness of the fundus will be absent. On proceeding to make a vaginal examination, we may find a tumour protruding from the vulva ; and if the placenta is attached to it, the character of the case is plain at once. The inversion may not have taken place until after the removal of the placenta ; in that case, we may tell that the tumour is in the uterus by its sensibility. The portion of the tumour to which the placenta was attached will be noticed to be rough, while the rest is smooth, and blood will be seen issuing from the uterine sinuses. The fact of a globular tumour lodging in the vagina or protruding externally, coupled with the absence of the uterus in the hypogastric region, and the severity of the constitutional symptoms, ought to be quite sufficient, in most instances, to enable us to diagnose inversion of the uterus

Treatment.—If it can be effected, the uterus should be immediately re-inverted ; and it seems to be a simple operation when undertaken directly on the occurrence of the accident. Every moment deferred increases the difficulty of re-inversion. The inverted fundus should be grasped and compressed firmly by the hand, and pressed slowly upwards. If the operation is to be successful, the tumour will be felt to yield and glide upwards up to a certain point, when the fundus will spring suddenly away from the hand and resume its proper position. When the uterus is inverted with the placenta still attached, should the latter be first removed, or should the uterus be replaced with the placenta *in situ?* Opinions seem pretty equally divided on this point. If I were to meet with a case of inversion, I should certainly feel disposed, first, to re-invert the uterus, and then to separate the placenta. By removing the placenta first, I should not be afraid so much of increasing the hæmorrhage, as of causing the uterus to contract, and rendering, in consequence, the re-inversion more difficult. If the uterus could not be replaced with the placenta attached, I should then of course remove it, and make another attempt. In those cases where an attempt to replace the uterus fails, the hæmorrhage must be arrested by applying cold to the inverted organ itself. Probably, pushing the uterus into the vagina would also assist in arresting the flooding. The walls of the vagina would act as a plug to the uterine sinuses, and irritate the uterus to contract. The collapse due to the accident and loss of blood must be combated by the free administration of stimulants.

Illustrative Cases.—As I have not met with a case of acute inversion of the uterus, I shall therefore quote one from the 'Glasgow Medical Journal,' and another from Ingleby's essay on that subject :—

I. Dr. Kelly, of Glasgow, delivered the patient, a primipara, after a lingering labour, by the forceps. As soon as the head was extracted there was a large gush of blood. He then goes on to say: "I then quickly asked the attendant at the bedside to lay her hand upon the belly, and without a moment's hesitation she somewhat rashly and roughly pressed both hands *into*, rather than on, the belly (it may be observed that in her right hand she held a towel, so that her fist was closed). This firm pressure seemed to arrest the flooding, and to have the effect of producing pain, as the body of the child (living) was expelled with very slight manual help ; but again hæmorrhage ensued, with sighing, restlessness, pulse extremely weak, and that exsanguine aspect, as well as general coldness of the whole surface of the body, which indicates imminent peril. Having given her a quantity of whisky and made her head level with her body, I passed my finger towards the vulva, which immediately touched what I supposed, and even considered the placenta ; but after tying the cord and separating the child from the mother, I laid my hand upon the belly ; but finding no hard or rounded uterus, the thought of what might be at once flashed across my mind. Accordingly, to my extreme regret, I found lying upon the bed this soft mass formerly felt ; and beneath the firm, hard, oval, unmistakable, entire inverted uterus, protruding quite externally. At this point, observing the dangerous condition of the patient, both from the shock of such an accident and from the exhausting loss of blood, I requested the assistance of my friend Dr. Tindal, who, I was aware, had had a similar case ; and his attendance, I am happy to say, was

prompt. Our first thought was that it would be best, and we even endeavoured before returning the displaced organ, to remove the placenta. To distinguish, however, placenta and walls of uterus, either by appearance or feel, and to separate the former with impunity to the latter, so firmly adherent whilst covered with blood, was a more difficult and hazardous task than one may feel disposed to credit, and than we were willing to risk. With right hand doubled up, therefore, I pressed steadily and firmly against the fundus, or most dependent part of the whole mass, which very soon began to yield and glide upwards, followed by the hand, until complete reduction and normal restoration was effected. The placental mass was now speedily and easily peeled off, in doing which the internal irritation re-excited the contractile powers of the uterus, and the retained placenta was expelled, with which the hand was withdrawn. Thereupon, more whisky was given, which soon rallied her from the shock and loss of blood." She recovered without a bad symptom.

II. "Mrs. —— was delivered of her first child on Thursday night, the 17th. The practitioner informed me (Mr. Ingleby) that, immediately on the removal of the placenta, syncope took place, followed by profuse hæmorrhage, which subsided a little the next morning. She was harassed by frequent vomiting, pain in the hypogastrio, and an occasional increase of hæmorrhage, until the succeeding Thursday night, the eighth day after delivery, at which time I was requested to see her. I found her nearly without pulse, exsanguine, comatose, delirious on being roused, and apparently moribund. On laying my hand over the pubic region, the uterus, which felt very hard, presented two singular features, its form being almost conical, and its circumference particularly small. I ascertained that the vagina was filled by a very bulky round tumour, which almost reached the os externum, corresponding to the fundus uteri, and resembling a very large-sized polypus. On carrying the finger as high as I could possibly reach, I distinctly felt the os uteri encircling the tumour like a firm stricture. It was clearly a case of inversion of the uterus, the body of the organ being above the brim, and the os internum occupying the centre of the inversion. Under the impression that the sufferer was dying, her relations resisted for some time our earnest entreaties to be allowed to make an effort for her relief. Yielding partly to persuasion and partly to remonstrance, they at length assented. In about five minutes the stricture gave way to the compression which was employed; the left hand gained full possession of the uterine cavity, the fingers being distinguished through the abdominal coverings by means of the right hand placed over the hypogastrium. A piece of placenta was felt adhering to the body of the uterus, but allowed to remain, the organ being then perfectly flaccid; and neither the presence of the hand within its cavity, with friction and a cold napkin over the hypogastrium, nor the administration of ergot and diffusible stimuli, produced the slightest contraction. The hand was therefore withdrawn, and the stimulating plan persisted in during twelve hours before the pulse could be distinguished. The return of the pulse was almost immediately followed by the return of uterine contraction and the expulsion of the piece of placenta, being about one-fourth of the entire mass, in a highly decomposed state. The following day the patient was wonderfully improved, and gradually recovered."

SUNDERLAND MEDICO-CHIRURGICAL SOCIETY.—A Society under the above title has been formed in this town under the presidency of Dr. Brown, J.P., with Mr. Dixon, J.P., and Dr. Parker as Vice-Presidents, and Dr. Yeld as Hon. Sec. and Treasurer. The objects of the Society are: The reading of papers, and discusions on all subjects relating to Medicine and the allied sciences, and mutual intercommunication respecting the prevalent diseases of the district. The exhibition of microscopic and other specimens of a physiological or a pathological character. To have power to take cognisance of all matters relating to medical ethics submitted for consideration.

ORIGIN AND NATURE OF SYPHILIS.

By RICHARD SAMUEL SISSON, M.D.

(Continued from page 70.)

A girl, having had connection with forty-seven men in twenty-four hours, and suffering in consequence from inflammation of the vagina, &c., was under the care of M. Rossignol. As no specific disease followed, the case is quoted by Mr. Acton as conclusive against Mr. Holmes Coote's opinion. Now, we have here a fair example of the inconclusive arguments by which theories are too commonly supported or opposed; for the means taken for subduing the inflammation, would put a stop to those processes by which the specific disease might have been produced. It is my opinion that much less intercourse, and milder results, coupled with neglect of cleanliness and treatment, would be most likely to give rise to the disease—as Dr. Watson says of purulent ophthalmia: "My own creed upon the matter is this, that the disease may and often does arise, independently of contagion, from the agency of ordinary causes of inflammation, and that having so originated it acquires contagious properties, which develop themselves only under circumstances that favour the propagation of most of the contagious complaints."—('Practice of Physic.')

Dr. Fergusson, in 'Notes and Recollections of a Professional Life,' says: "I believe with my friend Mr. Guthrie, that whenever prostitution is foul and unclean, restricted to few women amongst crowds of men, there the infection will be generated, which afterwards spreads through society at large."

Sir George Ballingall expresses his opinion that "syphilis may be developed in sound persons under particular circumstances, by the abuse of coition."—('Mil. Surg.')

Though combating such theories as these, Mr. Acton believes that syphilis originated from some poison introduced into the economy from animals, or decomposing animal matter.

I see no improbability in assigning the origin of this poison to the decomposition of the human secretions, or in attributing syphilis to the absorption into the economy of a poison extrinsically generated, precisely as we now believe pyæmia so called to be produced.

Professor Aitken says: "The history of small-pox is decisive against the notion of its spontaneous origin, and if of small-pox, so for all the other specific zymotic diseases of the same nature." I, however, would reverse the Professor's line of argument, and say, since it is proved that many zymotic diseases amongst animals, as well as in man, do arise spontaneously, so we may infer of the rest; and I believe we carry our incredulity much too far when we deny the possibility of such origin on the bare grounds that absolute proofs are wanting.

To this theory, however, the objection may be raised that, if syphilis is subject to the same laws as other diseases of a similar nature, how comes it that virtuous females and others who have not subjected themselves to the usual means of contagion are not as frequently affected by it as by these diseases.

It would appear, indeed, that such was formerly the case, for the writers of the sixteenth century have described the infection as being conveyed, like the plague, from one person to another.

Syphilis, however, is not what it then was; it is milder in all its phases; and I think we may conclude with Dr. Farr, that "the morbific principle of some diseases, including that of syphilis, is fixed;" or with Dr. Mason Good, that "the miasm of human effluvium is chiefly distinguishable from that of dead organised matter by being less volatile."—('Study of Medicine.')

Unity or Plurality of the Chancrous and Syphilitic Poisons.

Upon this subject opinions differ, much more than is generally supposed, as the following propositions will show:—

1. The hard chancre alone is the infecting sore.

2. Both hard and soft chancre are infecting, their character depending on locality alone.

3. The character of chancre is determined by constitutional influences solely.

4. The suppurating sore is not infecting, but can produce a hard chancre, which is.

5. The suppurating sore is not syphilitic at all.

6. Induration of a chancre is the first symptom of constitutional infection.

7. Chancres have nothing peculiar or specific, but are the offspring of filth, having their character modified by the texture affected.

8. All chancres are local, and never followed by constitutional disease.

Carmichael describes four or five different primary sores capable of producing constitutional symptoms.

Syphilographers have caused great confusion by treating of chancre and constitutional symptoms under the common title of "the syphilitic poison." The terms "chancrous" and "syphilitic" are, however, by no means convertible or synonymous, and I have treated of them together, merely for convenience' sake; besides, they are so intimately connected, that a different arrangement would lead to nothing but confusion.

Ricord says, that chancre no more means syphilis, than the bite of a mad dog means hydrophobia; and those who support the first proposition—viz., that the hard chancre alone is the infecting sore—believe in the unity of the syphilitic, but in the duality of the chancrous virus; whilst those who hold that both hard and soft chancre are infecting, their character depending on locality alone, maintain the unity of the chancrous, as well as of the syphilitic poison.

It will be sufficient for our present purpose to discuss the two following questions alone:—

Is there any fundamental distinction between hard and soft chancre? And are their results necessarily different?

Mr. Lee says: "The hard chancre, untreated by mercury, is invariably followed by constitutional symptoms; the soft, never:" and he supports the first proposition by what appears to me negative evidence of the weakest kind.

"A patient," writes that gentleman, "who considered himself well informed upon the subject of the characters of an infecting sore, presented himself in March, 1859. He had a sore on the right side of the frænum, which spread ultimately for about three-quarters of an inch along the urethra. As the sore extended it became surrounded by considerable indurations, and this, as it approached the urethra, terminated quite abruptly. It was then impossible to distinguish this induration from that which accompanies an indurated infecting sore, and the patient believed that his affection presented all the characters of a true Hunterian chancre. The history of the case, however, and the character of the secretion furnished different testimony; and the patient was prevailed upon, not without considerable difficulty, to be treated for a local affection. I ventured to assure him that his constitution would not be affected, and I had the satisfaction of seeing him Nov. 5th, 1860, and again Feb. 21st, 1862, without his having had any constitutional disease."

The following case, from Harrison on 'Venereal Diseases,' is to the same effect:—

"A young lady had on the right labium an ulcer with a well-defined edge, which proved troublesome, and took a long time to heal. At one period there was considerable thickening about it, so that I was almost inclined to look upon it with suspicion, and was almost thrown off my guard by its appearance. The hymen was perfect. . . . There was, in fact, nothing venereal about the sore; but if ever I saw a chancre, so far as external or visible characters are concerned, it was this." These two sores got well without mercury, were not followed by constitutional symptoms, and therefore, according to the views of these gentlemen, could not possibly have been indurated chancres; although both admit that, as far as external appearances were concerned, they were undistinguishable from such.

Mr. Lee trusted to the history of his case and the secretion furnished, both fallacious guides—the former, as given by the patient, not often to be depended upon; and the latter of no diagnostic value.

Dr. Bennett, of Edinburgh, one of the first histologists of the day, says: "No distinction exists between the different kinds of chancre and other purulent sores." Sigmund, of Vienna, also says no distinction exists. In Mr. Harrison's case the hymen was perfect—no unusual case in girls affected with both gonorrhœa and syphilis. (See several cases to this effect in 'Lancet,' 1859-60.

It is now well ascertained that mercury may postpone, but will not prevent, the appearance of constitutional symptoms; and it is also equally well known, that whatever treatment we adopt for the cure of chancre, no secondary symptoms may follow.

Galligo affirms that hard chancre untreated may be followed by no secondary symptoms. Diday remarks that secondary symptoms generally occur within three months after hard chancre not treated by specifics, if such are to appear; inferring thereby that such do not always appear under these circumstances.

Moreover, according to Marston, Hebra, and others, no constitutional symptoms may follow infecting chancre for many years, or the disease may remain latent in the father and yet be inherited by the offspring. The weight of evidence, then, appears to me against the proposition that "hard chancre untreated by mercury is invariably followed by constitutional symptoms."

Of soft chancre, Mr. Langston Parker says: "I believe that the simple non-indurating chancre occasionally gives rise to constitutional symptoms."

Contrasting the simple chancre with the sloughing and phagedænic, Mr. Erasmus Wilson says: "The calm and natural action present in the simple chancre being favourable to the development of the virus, renders it more dangerous as a source of constitutional infection."

Mr. Mayo says: "Although we now admit that local ulcers of another character are liable to follow impure intercourse, and *to infect the system*, still the opinion universally maintains its ground, that the appearances specified by Hunter are most decisive as to the nature of the disease."

And Mr. Harrison, going still further, writes: "Symptoms simulating those of constitutional syphilis, such as eruptions, sore throat, &c., may, if I mistake not, supervene on ulcers of the genitals not truly syphilitic."

Dr. Clerc, one of Ricord's pupils, considers the simple chancre only a modification of the infecting chancre; it is, he says, the result of the inoculation from an infecting chancre upon a subject already affected by constitutional syphilis. Each of these chancres transmits itself singly as a distinct pathological species.—(Maunder's 'Translation of Ricord.'

Ricord himself states: "The chancre with a soft base of syphilitic subjects is transmitted either as a simple or as an indurated chancre. Finally, it seems probable that the form under which it is reproduced depends on the nature of its origin, that is to say, on the chancre which gives birth to it."—(Ib.)

In other words, Dr. Clerc believes that the soft chancre is the result of the inoculation of the hard upon a previously infected individual, and that it retains this modified character under all circumstances; whereas Ricord believes that it is transmitted as a hard chancre to a previously healthy individual. At the same time, he considers the soft chancre here spoken of as analagous only in appearance to the simple chancre; so that, in order to escape from the dilemma in which he was involved by his dogma that "simple chancre is never followed by constitutional symptoms," Ricord has described as a different species of sore that which had always been considered synonymous with simple chancre—viz., "chancre with a soft base."

The inoculation test is, however, the *experimentum crucis* of those who deny the unity of the chancrous poison.

Professor Aitken says: "Mr. Lee and Rollet have shown that the infecting sore is not only incapable of auto-inoculation, but is not inoculable upon a person who has been contaminated by syphilis."

Mr. Lee says: "After the characteristic induration has been established, the infecting chancre is no longer capable

of being re-inoculated; but for a considerable time, if fresh action be excited in the part—as, for instance, by the application of a blister—a secretion may be obtained, which is re-inoculable upon the patient himself or upon another syphilitic patient."

Mr. De Meric remarks: "I often see patients who present a hard chancre behind the corona. This kind of sore secretes but very little pus in ordinary circumstances; but uncleanly habits and negligence excite irritation and inflammation, and pus is then pretty largely secreted. The groove behind the corona becomes inoculated, wreaths of chancres spring up, but none take on induration."

To be continued.)

SCIENTIFIC ARTICLES.

ON THE FEBRIFUGE PROPERTIES OF THE COMMON WHITE WILLOW.

It has long been known that the white willow and its alkaloïd, salicine, possess febrifuge properties, and the fortunate coincidence has often been remarked of the growth of the willow in those very localities where intermittent fevers prevail—namely, in low, marshy situations. Dr. Cazin remarks, that if the willow has failed to exert a febrifuge action in all cases, the circumstance is due to the smallness of the dose employed, and he suggests that the remedy should be associated with other bitter and aromatic vegetable extracts. M. Cazin has been in the habit of treating in this manner for the last twenty years the intermittent fever which prevails among the inhabitants of the marshy grounds about Calais; and he has found the willow an efficient substitute for cinchona and quinine. In the early stage he recommends an emetic or aperient, when gastric disturbance is present, and then he prescribes large doses of the bark of the white willow, alone or in combination with camomile, wormwood, and some other indigenous tonics, alteratives, and aromatics. He considers that the combinations of vegetable bitters with astringent and aromatic substances are far more efficient than the indigenous febrifuges administered alone. He also thinks it desirable to persevere for a week or ten days in the treatment after the removal of the paroxysms, and to prescribe a large dose every week for a month or longer, if any symptoms indicate the danger of a relapse. M. Cazin recommends the willow bark to be employed in a decoction (℥ss to ℥j in a pint of water) or in powder in the dose of ʒij to ℥j, in wine or beer, or in the form of a tincture or extract.—DR. SEMPLE'S 'Report on Materia Medica and Therapeutics,' in the 'British and Foreign Medico-Chirurgical Review.'

ON THE THERAPEUTICAL APPLICATIONS OF THE SOLUTION OF THE PERMANGANATE OF POTASH AND OF OZONE.

Dr Jackson having ascertained that the disinfecting and deodorizing properties of the solution of permanganate of potash had been established, determined to test its therapeutical action and practical application. He found, by experiments on himself, that the solution had no proper taste, but gave a sensation of coolness in the mouth, leaving behind a slight styptic feeling and dryness, which continued for an hour or more. When taken in the dose of a teaspoonful, slightly diluted, two or three times a day, it caused no inconvenience, but it was somewhat diuretic, and increased the appetite. He prescribed the solution in a case of dyspepsia, attended with loss of appetite, disordered digestion, and extreme lassitude. The patient was directed to take a teaspoonful in half a wine-glassful of water four times a day, and in a few days he was quite well. Four cases of a similar character were treated in the same manner, with a rapid and successful result. Dr. Jackson relates other cases in whtch the solution of the permanganate was equally beneficial, one being a case of abnormally large secretion of urine. But the most remarkable and almost marvellous effects of this salt are observed in the treatment of gangrenous wounds, and for this purpose it has been employed in several of the hospitals in the United States. Having thus proved the decided therapeutic action possessed by this substance, Dr, Jackson endeavoured to ascertain its active principles, and with this view he tested it for oxone, which he found in great abundance. He regards the solution of permanganate of potash as containing, besides the salt itself, ozone (which is an allotropic form of oxygen) and the peroxide of hydrogen, which may be regarded as water in combination with *antozone*, another allotropic form of oxygen. These bodies possess the power of arresting the process of disorganisation in living tissues, and arousing the vital action in decaying structures. — Dr. SEMPLE'S 'Report on Materia Medica and Therapeutics,' in the 'British and Foreign Medico-Chirurgical Review.'

HOSPITAL REPORTS.

BY DR. G. DE GORREQUER GRIFFITH.

KING'S COLLEGE HOSPITAL.

CASE OF STONE IN THE BLADDER.

Wm. K., æt. sixty-two, unmarried, was admitted on Feb. 4th, 1864, under the care of Mr. Smith.

History.—Has always been a healthy man, except that he had an attack of erysipelas in the autumn of 1862: the parts affected were the head and face. He remarked that at the time of his illness the urine was very thick, but he took no notice of it. He has always been abstemious. About a month since he passed a good quantity of blood with his water, which lasted, in a greater or less degree, until the time of his admission. He applied to Mr. Smith, in the out-patient department, with the usual symptoms of stone. He was sounded and the stone detected, and a few days afterwards he was admitted.

Feb. 6th.—The patient being under the influence of chloroform, Mr. Smith made the usual lateral incision on the left of the mesial line, making a rather free incision. The staff which had been previously introduced was quickly cut down upon, and the point of the knife entering the groove was made to pass rapidly into the bladder. The prostate was found to be very large. Mr. Smith then passed in the forefinger of his left hand and detected the stone lying in a kind of pouch on the left of the prostate; a pair of moderate-sized forceps was then introduced, the stone seized, and quickly extracted. The patient was then returned to bed. The calculus was fully equal to the size of a large plum and was of that peculiar kind termed the mulberry.

In the evening of the day of operation hæmorrhage into the bladder was found to have occurred, and a clot having been formed the water was found not to pass through the incision: the House Surgeon, however, drew off the urine, and a tube was then placed in the opening to allow the water to drain off.

Feb. 7th.—The hæmorrhage still continues, and cold was applied. The water was again drawn off. He seems to be pretty well. Ordered

Ammon. sesquicarb., gr. v.;
Spts. ammon. aromat., ℥ xx.; N.B.
Mist. ether. chloric, ʒ i., omni horâ quarta.

8th.—The bowels were very much confined, so an enema of about a pint of gruel with an ounce of turpentine was administered. The hæmorrhage has ceased, but the water does not flow readily by the opening. The tube was removed.

10th.—The enema caused a free evacuation of the bowels: he seems very low and has some bronchitis. The water was again drawn off.

12th.—He appears better this morning, but suffered a good deal of pain in the bladder, the water not coming away at all freely by the wound. The House Surgeon again drew off the water, from which the patient experienced great relief; he is, however, troubled with flatu-

lence, and does not pass his motions with ease; his pulse is 95, and occasionally intermittent; he is, however, better than he was on the 10th.

15th.—There is a swelling over the right parotid region, as though an abscess were forming. The water comes chiefly through the urethra; he is very weak and low.

17th.—Pulse 112; tongue very dry: he is altogether very low, and there is a good deal of bronchitis and of difficulty in expectoration. The swelling near the ear is poulticed.

19th.—Pulse 96; tongue is dry, red, and cracked: the parotideal swelling has greatly increased in size, and now extends down as far as the angle of the jaw: there is also some œdema of the lower right eyelid. The water comes a little now by the wound.

22nd.—Ordered

Quinæ disulph., gr. xii.;
Acid sulph. dil., ℥iss.;
Aquæ, ℥viii., ℥i., ter in die.

Pulse is 112, but he seems much better; more water now passes by the wound: the parotideal swelling is still large, but the œdema of the eyelids has subsided.

24th.—To-day there is a small opening just over the angle of the jaw; very little discharge issued from it. The bowels have been relaxed for several days and yesterday they began to relieve themselves involuntarily: the log-wood mixture was given without avail, and to-day he is ordered

Tinct. krameriæ, ℥i.;
Acid sulph. dil., ♏x.;
Tinct. opii, ♏v.;
Decocti hematoxyli, ℥i., secundâ quâque horâ.

25th.—Last night the abscess opened into the external auditory meatus, and there has been a thick but scanty discharge of healthy pus ever since; he is better since this occurred. The diarrhœa still persists. Ordered to take

Tinct. kino, ℥ii.;
Confectionis aromat., ℈ii.;
Decocti hematoxyli, ℥i., tertiâ quâque horâ.

26th.—The diarrhœa is not quite so bad; pulse is 96; tongue is dry and red; there is more discharge from the ears.

March 1st.—Passes no water from the wound: there is a red blush around it: he is ordered to have poultices applied to it. The discharge from the ears is less.

16th.—Poultices discontinued: the discharge from the ears has very nearly ceased and is now dressed with the simple water application.

20th.—The discharge has quite ceased: he is now able to sit up.

April 1st.—He is nearly quite well in every way, and is gaining strength. There are no symptoms of stone.

5th.—He is discharged, cured.

Fistula in Ano.

J. D., æt. twenty-six, by trade a tailor, was admitted under the care of Mr. Smith, the date of his admission being March 11th.

History.—Six weeks since he noticed a swelling in the perinæum, which burst in a day or two from the time it was first observed: this swelling proved to be an abscess, and discharged freely. It is on the right side and rather in front than behind. A fistula has resulted from the abscess.

March 12th.—Mr. Smith divided the fistula and treated it in his usual manner.

16th.—No hæmorrhage since the operation, and he is to-day discharged, cured.

WESTMINSTER HOSPITAL.

We have lately noticed two very interesting cases of operation, under the care of Mr. Barnard Holt, in which he has employed fine wire as a substitute for thread in ligaturing the arteries that required to be secured. The first case was that of A. C., who was admitted under Mr. Holt's care, suffering from carcinoma of the left breast, of two years' duration. The tumour presented all the usual characters of scirrhus, was hard and heavy, and had latterly become adherent to the integument and slightly so to the pectoral muscle. The glands in the axilla were not affected, but she suffered continually from a lancinating pain in the breast, extending down the inner side of the arm.

Mr. Holt removed the whole breast, dissecting the mass cleanly off the pectoral muscle, the fibres of which were exposed and quite cleared from any cellular attachment: a small portion of the muscle was also removed where the tumour was adherent. Seven arteries were ligatured with fine wire, *and both ends were cut as short as possible;* the edges of the incision were accurately approximated and retained by wire sutures. *No strapping was employed,* but a pad and bandage were applied only sufficiently tight to retain the surfaces in apposition. On the second day after removing the pad the wound was found to be firmly agglutinated; the sutures were removed on the fifth day, the wound, a very small piece excepted, having united by the first intention.

The second case was that of J. Barratt, who, seven weeks previously, met with an accident resulting in a compound fracture of the leg. The patient was a large flabby man, and although every effort was made to preserve the limb the case did not proceed satisfactorily; and subsequent rigors, with great exhaustion and a very rapid pulse, necessitated immediate amputation. Mr. Holt removed the limb above the knee by the flap operation. The *femoral* as well as the other arteries, six in number, were ligatured *with thin wire and the ends were cut short,* and, as in the former case, the incised edges were retained in apposition by interrupted wire sutures. Strips of lint wetted in lukewarm water being used instead of strapping, the wound was kept approximated so long as the wires would hold; and when they cut themselves out a considerable amount of union had taken place. There was very little suppuration; the surface presented a healthy aspect, and was as vascular as could be expected in a man who had undergone exhausting suppuration previous to the amputation. Upon examining the limb, the tibia was found stripped of its periosteum as high as the knee, which joint contained a considerable quantity of pus, and the cartilages had commenced to ulcerate.

Mr. Holt remarked upon the interest attaching to these two cases—first, with regard to the importance of removing the whole mammary gland, together with its cellular connections, however small the malignant growth might be. He mentioned that, in four cases where he had fully carried this out, the patient as yet, now four years since, had not any return of the disease. The subject of occlusion of the bleeding vessels with thin wire, and cutting both ends short, appeared to possess some advantages. The edges of the wound could be accurately approximated, and, in ordinary healthy persons, tended to promote union by the first intention; the after dressing was much more simple, and the patient was saved the pain of removing threads, which frequently did not become disengaged for a considerable period of time, leaving tracts to be afterwards healed by granulation. Mr. Holt stated he had now employed this means of treatment in several cases with the best result, the patient merely complaining of slight pricking sensation for a few days after the wound had healed. He expressed his intention of substituting unmanufactured gut for wire in his next operation, and thus, in all probability, the slight pricking sensation might be avoided.

Projected Fever and Small-pox Hospitals in Paris.—There is some agitation going on among hospital physicians of Paris respecting the advisability of taking a leaf out of our book. It is customary, in that capital, to place fever and small-pox patients into the general wards, regardless of the risk thereby incurred by the other patients. The authorities now seek the advice of the medical officers touching this matter, and it is extremely likely that at least separate wards will be assigned to patients labouring under the affections above named. We are informed that the question is being elucidated mainly by the collection of facts obtained in London, Mr. Marson, of the Small-pox Hospital, having been specially applied to.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JULY 6TH, 1864.

DR. OLDHAM, PRESIDENT.

The following gentlemen were elected Fellows of the Society: Dr. Ed. Williams, of Wrexham, and Dr. W. G. Houghton, of Mount street.

MR. HARPER exhibited an Ovarian (?) Tumour removed that day by Mr. Baker Brown. The nature of the tumour being a matter of doubt, the specimen was referred to Dr. Greenhalgh and Dr. Braxton Hicks, in conjunction with Mr. Harper, for special examination.

Dr. SNOW BECK exhibited a Uterus removed from the body of a woman who died on the ninth day after a natural labour, and who presented all the symptoms of a severe form of puerperal fever. The peritoneum was found inflamed after death, and about two pints of turbid fluid existed in the cavity of the abdomen. After a minute and careful examination of the organ, the sinuses, the pelvic veins, the lymphatics, as well as every other tissue, were found perfectly healthy, and the internal cavity everywhere covered by a soft membrane, containing the usual microscopic elements of the mucous membrane. A decided negative was thus given to many of the supposed causes of puerperal fever. But it was shown that the sinuses and pelvic veins permitted air to flow along their cavities, and that a ready means thus existed for the purulent infection of the general system. This open state of the sinuses was further traced to an imperfect contraction of the uterus after the birth of the child, which thus allowed fluid to pass along these canals.

Dr. MURRAY showed a specimen of Fibrous Tumour of the Uterus. It was interesting from the fact of its growing entirely in the posterior wall of the cervix uteri, without involving in the least degree the body or fundus of that organ. The internal os could be distinctly felt, and sharply separated the sound from the diseased tissue. The patient was in too weak a state to admit of any operation, or that of enucleation might possibly have removed the mass, which was larger than an orange.

Dr. MARION SIMS, who was present, in reply to a question, stated that he had practised in certain cases incision of the os uteri for the purpose of restraining the hæmorrhage often present in cases of fibroid tumour of the uterus. His results had been satisfactory; but he had not practised it sufficiently often to be in a position to speak decisively as to its absolute value. He disclaimed originality as to the operation itself.

Dr. GREENHALGH exhibited a Pelvimeter made by Mr. Ferguson during the year 1859, which so closely resembled the instrument lately described as a "New Pelvimeter," the invention of Drs. Earle and Murphy, that he felt it due to his colleague, Dr. Harris, to state that this instrument was devised by, and manufactured for, him nearly five years ago.

Dr. ROBERT GREENHALGH read a paper

ON PLACENTA PRÆVIA.

The author first alluded to the large mortality both to mothers and children (one in four and a quarter of the former, and about two-thirds of the latter), which he attributed mainly to the severe and repeated losses of blood, to the delay in effecting the delivery, and the method of turning usually had recourse to in these cases. He then gave the details of twenty-four cases which had occurred in his own private and consulting practice between the years 1842 and 1864. He placed before the Society several statistical tables, chiefly taken from Dr. Read's work, to show, in addition to other facts, that the expulsion of the child generally takes place before the full period of utero-gestation—premature labour being the rule and not the exception; that Nature, unaided, frequently terminates the delivery with safety both to mother and child; that complete and partial artificial separation of the placenta before the birth of the child has failed in numerous cases to arrest the hæmorrhage; and that these methods and turning had proved most unsatisfactory in their results. Having dwelt at some length upon these several points, he strongly advocated a close observance of the way in which Nature terminates these cases with safety to mother and child. Having specified the result of his observations on that head, he confidently recommended the following plan of treatment, which had proved, as far as the limited number of cases could prove, in his hands and in those of others, far more successful both to mothers and children than any other method hitherto devised. It was as follows:—1st. That in any case of hæmorrhage, whether profuse or otherwise, occurring after the commencement of the seventh month of utero-gestation, ascertained to be due to placenta prævia, artificial premature labour should be induced at once, or as soon as the condition of the patient will admit of it. 2ndly. That, in order to effect that end without a loss of blood, an air-ball, covered with spongio-piline, be passed, collapsed, into the vagina, and then inflated so as effectually to fill that canal, while a bandage is placed firmly round the abdomen; at the same time the ergot of rye and borax are to be administered in repeated doses. He further recommended as aids, stimulating enemata, with tincture of nux vomica, galvanism, and friction over the abdomen. The author concluded by condemning, in the strongest terms, the use of general hygienic means and hæmostatic remedies over days and weeks in these cases, which course he was firmly convinced, was the cause of many valuable lives being lost.

Dr. BARNES observed that, agreeing generally in the principle that labour should be brought on in cases of severe hæmorrhage from placenta prævia—a principle, he believed, commonly acted upon in London,—he could not assent to much of Dr. Greenhalgh's reasoning, or concur in approving his plug. His statistical reasoning was open to criticism. He assumed two postulates—first, that the mortality of placenta prævia was 1 to 4½; secondly, that the mortality from inducing premature labour was one in 53; and he drew the extraordinary conclusion, that by always inducing labour we might substitute the low mortality of premature labour induced under selected circumstances for the assumed heavy mortality of 1 to 4¼. Now both the postulates were false, and the conclusion was manifestly illogical. The mortality of 1 in 4¼ drawn from Dr. Read's tables was a most unfair representation of the results of modern obstetricy. He (Dr. Barnes) had analysed his own cases. Since the publication of his Lettsomian Lectures 59 cases had come under his own observation; and he drew 24 from other sources, most of these last being treated upon his (Dr. Barnes's) principles. The deaths were six only, or 1 in 14. And if he were to follow Dr. Greenhalgh in striking out the fatal cases on the ground that treatment was too late, he might show statistical results very far superior. He should have, not 10 successful cases, but 77. Two of his cases died of pyæmia, having been treated by by forced delivery—that is, in direct opposition to his principles; 2 were moribund when seen, and 3 were hopelessly anæmic. He had taken all cases as they occurred in his books without selection or arrangement, yet 26 cases fell as an uninterrupted series of recoveries, which he might fairly place against Dr. Greenhalgh's selected 10. Then as to the mortality in premature labour. Premature labour was induced under selected circumstances to avoid dangerous complications. Such cases were not to be compared with labours forced upon us by the flooding of placenta prævia. This Dr. Greenhalgh disregarded. But surely placenta prævia went for something. Then the children. Dr. Greenhalgh had been fortunate. In his small series of 10 cases he had eight living children. He (Dr. Barnes) ventured to say that a larger experience would modify this result. Many dangers surrounded the child in placenta prævia: cross-birth, funis presentations, immaturity, and asphyxia in utero; some were born putrid. His (Dr. Barnes's) plan was eminently adapted to secure the child. But his mortality was ·63. The very method of Dr. Greenhalgh of bringing on premature labour must of itself often destroy the child, for the floodings would come

on at six and seven months. And in some cases flooding did not occur until the end of gestation. These were often the most dangerous. Yet here Dr. Greenhalgh's plan was not available. And what was Dr. Greenhalgh's plan? The use of a *vaginal* plug, not differing essentially from the colpeurynter of Braun. It acted like all other vaginal plugs, by exciting uterine contraction, if the uterus was excitable. But unfortunately in the worst cases the uterus was paralysed. In these, where art was most necessary, the plug was useless. He was surprised to hear Dr. Greenhalgh undervalue rupturing the membranes. This simple method was in many cases quite sufficient, and no method was long serviceable without it. If in combination with rupturing the membranes, the placenta was detached from the cervical zone, so freeing the cervix, the cervix then artificially expanded by his *cervical* dilators, and the bimanual method of turning resorted to, he was confident, from large experience, that a greater measure of success would be obtained than by any other especial method. He took that opportunity of stating that the first published case of the use of the intra-uterine dilator in placenta prævia which attracted his attention belonged to Mr. Jardine Murray, of Brighton.

Dr. Hall Davis remarked that he had little faith in statistics of placenta prævia representing a mortality of one in three or four from that complication, knowing that former statistics to that effect had included cases originally published, not to show the average mortality, but as selected instances for the most part hopeless when first brought under medical observation, and intended to prove the fatal tendency of this complication of pregnancy if not timely seen to. He would also observe that we are not left without authority, laid down in lecture and works of reputation, to convince us of the dangers of delay in placenta prævia, and guide us to efficient treatment. He might refer, for example, to the lectures of the late Dr. D. D. Davis at University College from 1828 to 1841, and to his esteemed System of Obstetric Medicine, which taught no temporizing treatment, but, on the contrary, the necessity of early and active interference, while at the same time pointing out the hazards of a forced delivery through a rigid os uteri. As to his own experience, he might state that in the Royal Maternity Charity alone he had had, from 1842 to 1862, as physician of the western district, twenty-four cases of placenta prævia. In that number twenty-two mothers were saved, and the two deaths would have been averted had the injunctions given been observed. His treatment had varied with the case. Thus in *partial* placenta prævia he had found the simple discharge of the waters usually sufficient. When the flooding has not been thus arrested, and delivery has been impracticable by reason of the small size of the uterine orifice, he has plugged the vagina impactedly with sponge, or with a sufficient quantity of other suitable material at hand. He has then waited in security for the first opportunity of acting if necessary. In many cases, on withdrawing the plug, the head was found descending, and the birth was quickly completed without further aid. In cases of *entire* placenta prævia, when the os uteri would not admit of delivery, he also resorted to the plug, and of similar materials as before, believing such a plug, from its solidity, when efficiently applied, to be far superior to any elastic dilator. After from two to six hours he was generally enabled to remove the plug and deliver by turning. In this operation he preferred to pass his fingers in by the side of the placenta, where it might already be detached, to perforating its centre, as some have recommended, as this latter mode necessitates a more considerable injury of the placenta vessels and further hæmorrhage. In the operation of turning, it had been his usual practice to fix the uterus by the right hand applied externally on the abdomen while turning with his left hand. To Dr. Hicks, however ('Obstet. Trans.,' vol. v.), were we indebted for a definitely combined mode of *external and internal version* by acting on the opposite poles of the child, the breach above being depressed by the external hand, while at the same time the presenting head is pressed upwards and to its own side. Then the feet are lowered to the os uteri and one or both brought through; the risk, so especially great in flooding, of passing the hand into the cavity of the uterus, being in this way avoided. In conclusion, he might say that, while he differed from the author on the points to which he had referred, he fully concurred with him, as all judicious practitioners must do, that to delay efficient interference in this complication is most hazardous.

Dr. J. Braxton Hicks quite agreed with Dr. Greenhalgh as to the necessity of inducing labour in placenta prævia as soon as arrangements could be made, which he believed to be the plan adopted by all who saw much midwifery in this city; it was the practice he had always adopted. With regard to the statistics quoted from Dr. Reid's work, he quite agreed with Dr. Barnes as to their want of value. All large groups of statistics were utterly useless as a guide of any particular practice. It was absolutely essential that the details of the cases should be known. In the tables presented to the Society it was impossible to say what were the surroundings of the patients; whether, in fact, they had died from the operation, from the hæmorrhage, or from the subsequent calamities to which it was known cases of placenta prævia were exposed. How, therefore, could we tell the value of any particular plan of treatment without this information? He considered that when it was said the death-rate was 1 in $4\frac{1}{4}$, there must be some mistake as regards present practice. In the Guy's Hospital Charity it was for nine years at 1 in $7\frac{1}{2}$. He also was obliged to differ from the assertion that the life of the child was not influenced by placenta prævia. That it was so he had no doubt; for in half of the cases he had seen where it was made out clearly, the child was known to be dead before any operation was attempted. He hoped the author would have alluded to the plan which he (Dr. Hicks) had recommended in his recent paper "On Combined Version," because he felt sure that it was a very useful one, and not difficult to anyone who would take the trouble to learn it. He had known at least nineteen cases, many of them very severe, in which it had been used, with only one death, and that arising from extreme hæmorrhage before seen, and which could not be put down to version. In all his cases there had been immediate cessation of bleeding as soon as the breech was in the os, and he had found that almost in every case labour pains expelled the child within two or three hours from the commencement of the operation. This point it was important to know in order that we might make our arrangements accordingly. The child was a most efficient plug, and it could be brought down as soon as the os would admit a finger or two. With regard to the small size of the os preventing turning in the above-mentioned mode, he could say it must occur but seldom; when it did so, the detachment of placenta round by one finger generally liberated it considerably, enough at least to introduce two fingers; if not, the elastic bags could be used with much advantage. We must judge of treatment by its practical application: our hands we have always with us, whereas if called to a case at a distance from home, or in great hurry, it would be impossible sometimes to obtain the plug now shown. The effect of version upon the life of the child he could not compute. Doubtless cephalic was the best presentation; but he had not found in his cases any great mortality. The important point was not to hurry the case after the breech was in the os. The child was generally destroyed by drawing it down before the os uteri was open sufficiently. When the breech was in the os, the case in almost every instance might be left to nature, adopting the rule as in breech cases.

(To be continued.)

Brechin: Munificent Bequest.—A meeting has been held at Brechin for the purpose of taking steps to secure the gift of 1,000*l.* bequeathed by the late Dr. Don, of Bearehill, for establishing an hospital or infirmary and dispensary at Brechin, provided another 1,000*l.* should be raised. The Earl of Dalhousie presided, and promised 100*l.* towards this object; Sir James Campbell, of Stracathro, has also given 100*l.* The total amount subscribed is 275*l.* It is expected that 600*l.* belonging to the funds of the old dispensary will be available for the new institution.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 17, 1864.

THE 'TIMES' ON MEDICAL MATTERS.

The leading organ of the daily press has lately devoted considerable space and some attention to matters of a Medical nature; and from the great circulation which it possesses, all that appears in its columns is sure to gain a large number of readers, and to produce some impression, however transient, on the public mind. It is very much to be regretted that, when treating of Medical subjects, the editorial department does not take care to exercise some supervision upon the quality of the articles inserted, so that erroneous notions may not gain currency. Such care is especially necessary in the case of Medicine, in the practical details of which the old adage of "A little learning is a dangerous thing" finds frequent verification. Many years ago, not only much misapprehension, but also much positive mischief, was caused by the promulgation in the 'Times' of a supposed new remedy for malignant cholera, in the shape of castor-oil; and only last year the same Journal lent its pages to the glorification of a pretended cure for small-pox, in the form of an American indigenous plant, which is possessed of no efficacy at all. If the 'Times' were a scientific Journal, prepared to strengthen or recant its opinions according to the dictates of experience and the testimony of the learned, the appearance of mistaken views in its pages would not leave so much to be regretted; but as, whether wrong or right, its policy is never to avow that it has been in error, it is absolutely necessary for the Medical press to expose the erroneous views to which it too often gives currency, and thus to warn the unsuspecting and too credulous public against the reception of doctrines which may, if acted upon, lead to dangerous or fatal consequences.

These remarks have been suggested by the perusal of two letters, both purporting to be written by Medical men (although they are anonymous), and which appeared last week in the pages of our daily contemporary. The communications are of a very different character from one another, and on two totally different subjects; and while one is characterised by remarkable good sense, the other is marked by exactly the opposite quality. The one is "On the Supply of Medical Officers for the Public Service," and the other is "On Chloroform." The accidental juxta-position of these letters in the same journal on the same day must be our excuse for treating of them together.

The writer of the first letter, signing himself "F.R.C.S.," gives a very intelligible account of the reasons which dissuade young men from entering the service of the Army and Navy, namely, because they do not obtain so much social consideration and so much substantial remuneration in those services as they can gain elsewhere. He also combats the notion that the Profession is overstocked at the present moment, and he proves very clearly that it is not. We cannot forbear from quoting our own remarks, made in a leading article of this Journal so lately as Aug. 3, and of which the letter of "F.R.C.S." is little more than an illustration and an amplification:—

"The Army Medical Service remains in the same position as before. A large number of vacancies exist, and candidates are deficient; and of those who offer themselves for the competition, many fail to pass the examination, and those who do pass are mostly in the third class. That this result is in great measure to be attributed to the dissatisfaction existing against the Army authorities, is indubitable; but it is not true that the Profession is so overstocked as to render the Army Medical Service under any circumstances a very desirable boon to the Medical aspirant of the present day. The real fact is, that the junior ranks of the Profession are not at present overstocked, and the number of medical students is smaller than it was some years since, while the demand for young medical men is greater; but the necessity of a better education, especially in the preliminary branches, and the stringency of competitive examinations, have deterred many young men from entering upon a medical career, the emoluments of which are unlikely to remunerate them for the expenses they must incur and the time they must wait before profitable employment can be expected."

The writer, in fact, proceeds to show that, although the ranks of the Profession were crowded some twenty or thirty years ago, and young Medical men were then eager to obtain any appointment which was open to them, such is not now the case; and that while the population of the British Empire has largely increased, and our colonial possessions have augmented in number and importance, the pass lists of the different Medical Licensing Boards do not display a greater number of successful candidates than heretofore. Hence, it is evident that the demand is now greater than the supply; and it is a well-known fact that, independently of our own islands, our merchant vessels, our steam fleet, and our colonies and possessions in the distant seas, employ a large number of Medical men, many of whom are probably enjoying larger incomes and a greater amount of social respect than would be accorded to them either in civil practice at home or in the Army or Navy Medical Service. This is, in fact, a very healthy state of affairs for the members of our Profession, who, being in smaller proportional numbers and possessing a higher degree of education than formerly, will be able to obtain better terms for their professional services, and a higher rank than they formerly possessed.

The other letter in the 'Times' is "On Chloroform," and is in the worst possible taste; and unless promptly exposed, and its assumptions contradicted, may lead to irreparable mischief, by disseminating false notions upon a subject which is of paramount importance to suffering humanity. While our most learned physiologists, aided by practical physicians and surgeons, are endeavouring, cautiously and laboriously, although not yet with full success, to develop the causes of death from chloroform, and to devise means for averting such dangerous accidents in future,—at this period, on the principle that "fools rush in where angels fear to tread" (we make no personal allusion, for we know nothing of the writer of the letter), one who signs himself "*Chirurgus*" sets at nought the deductions of science and the results of general experience, and, resting his opinions

upon the results of his own practice, assumes to enlighten the English public upon what he considers to be the mismanagement of his fellow-practitioners.

He asserts that he has observed some 5,000 or 6,000 cases in which chloroform has been administered, and that he has never yet met with one that proved fatal. This may be perfectly true, and we believe it as fully as we do Dr. Humphry's statement, made in his lecture lately delivered to the British Medical Association, that no fatal case from chloroform had occurred at Cambridge. But yet this favourable result in the case of "Chirurgus's" practice may be the result of good luck rather than of good management, and we are the more inclined to think so when we read the remarks that follow. He proceeds to tell us that he takes no care in the discrimination of his cases, makes no inquiries into the patient's condition, is never deterred by the information that the heart is diseased, uses no apparatus for inhaling the chloroform, and takes no pains to have the assistance of a skilful administrator of the anæsthetic. He tells us that he uses no apparatus except a thick towel, held loosely over the patient's face, and always trusts the administration of the chloroform to the ordinary hospital students, "who, without any special training, simply follow the steps of those preceding them."

"Chirurgus" then informs his readers that the fatal effects of chloroform depend not upon peculiarities of individual constitution, but upon faults in the mode and management of administration; and that the Profession and the coroners' juries are entirely wrong in supposing that fatty degeneration of the heart has anything to do with the fatal result. He then suggests, in a tone of arrogance which cannot be too severely censured, that "a few convictions for culpable homicide would greatly promote the adoption of sound principles."

Having thus proved to his own satisfaction the superiority of his own practice, and the culpable negligence or ignorance of his professional brethren, he then propounds his own views as to the physiological reasons of death from chloroform; and here he displays such a want of knowledge on the subject as to deprive himself of all claim to the support or countenance of the Profession. He, in fact, alleges that death from chloroform arises from suffocation, and that the error at present committed is to watch the circulation instead of the respiration; and that, by a careful attention to the latter function, all danger would be averted. In a medical periodical it is almost needless to expose the fallacy involved in this view, and it is to be regretted that such erroneous statements should go forth to the general public in the columns of a newspaper. The truth is, that in many, if not most, of the cases of death from the administration of chloroform the heart has been the organ first and essentially involved, and that death appears to have resulted from syncope and not from suffocation. To adopt measures, therefore, to obviate the latter condition, while the patient is dying from the former, would be to cut off all chance of the patient's recovery; and he who would advocate such erroneous proceedings must be wofully uninformed even on the practical details of a subject on which he professes to enlighten the community.

SUMMARY OF THE WEEK.

THE MEDICAL PROVIDENT FUND.

The proposal to establish a Medical Provident Fund has met with almost unanimous approval at the late meeting of the British Medical Association at Cambridge. It is needless to expatiate on the value and importance of such a Fund to the Medical Profession, who, perhaps more than any other calling, are exposed to losses entailed by sickness and accident. A comprehensive scheme of affording succour to our unfortunate Medical brethren ought, of course, to include the provisions of a life assurance, and of the extension of assistance to Medical men when overtaken by sickness; but it has been practically found that, in order to insure the success of the proposed plan, the feature of life assurance must be abandoned, and that relief in sickness cannot be extended to persons above sixty years of age. Under these restrictions, the efficacy of the Provident Fund must necessarily be very much curtailed; but we cannot refrain from expressing our opinion that it would be unsafe to attempt more than is at present proposed. Some difference of opinion has been expressed upon the question whether the membership of the Fund should be restricted to members of the British Medical Association, or should be open to the whole Profession, but it appears to us that the latter would be the most proper course to pursue; for we must emphatically impress upon our readers, and upon the Profession generally, that the greater the number o those who join the Fund the greater will be its chance of prosperity. Two hundred members to start with will, we believe, be sufficient; but we apprehend that at least a thousand will be necessary to constitute the Fund upon a firm basis, and guard against the risk of failure.

THE HEALTH OF OUR WATERING-PLACES.

At the present season of the year, when all the population who can afford the time and the expense are rushing off to the sea-side, or to other supposed resorts of health, the public mind has been startled with some results obtained from the returns of the Registrar-General, and which seem to militate against some of our preconceived views as to the relative salubrity of certain watering-places. Thus it would appear that the places with a mild and relaxing climate are more healthy than those which possess a more bracing air, as may be seen from the fact that in the Isle of Wight the deaths average 17·1 in 1,000; the sub-district, including Ventnor, 15·4; Torquay, 17·1; Eastbourne, Seaford, 17·3; Hastings and St. Leonards, 18·3; Ramsgate and Broadstairs, 19; Brighton, 22, Whitby, 22·1; Margate, 22·3. But one of the clergy of Ramsgate, writing to the 'Times,' points out that there is an important fallacy underlying these returns, because the census is always taken in April, when all bracing places are empty of visitors, and all relaxing places are full. In Ramsgate, for instance, the

resident population is about 12,000, but at the present period of the year it expands to nearly 20,000 ; and it is argued that it is unfair to reckon the deaths of non-residents among the returns. The clergyman alluded to shows that, deducting the deaths of non-residents, the average of deaths in Ramsgate is only at the rate of 15·25 in 1,000, the lowest average in England for the preceding ten years ; that of Ventnor being 15·4. The returns of the Registrar-General will, however, be of great service in causing our sea-side towns to exercise increasing vigilance in removing sanitary defects, if any exist ; or, if they do not, in maintaining the standard of salubrity which they have already attained.

POISONING BY THE CALABAR BEAN.

The first instance, we believe, of poisoning by the Calabar bean in this country occurred last week in Liverpool, when no less than sixty children, who accidentally partook of these seeds, were seized with dangerous symptoms, and one died. Until we received the report of this case, we were not aware that the beans were imported into this country as an article of commerce ; and, indeed, when the researches upon the peculiar effects of the beans in Medical practice were being carried out, we understood that they were very scarce, and that specimens of them were procured with difficulty. In another part of our Journal we have related the particulars of the poisoning, and it appears that the toxical effects are those of a narcotico-acrid, and not of a pure narcotic as opium, although the Calabar bean resembles opium in causing contraction of the pupil. The treatment seems to consist in the administration of emetics to expel the poison from the stomach, and of stimulants to rouse the vital powers.

TELEGRAPHY AND THE CAMBRIDGE MEETING.

Our contemporary the 'Lancet' has beaten old Time himself completely hollow, for it has achieved the remarkable feat of reporting a lecture, printing it, and publishing it, before it was delivered ! Such is positively the fact, for Dr. Humphry's Lecture on Surgery, delivered by that gentleman on Friday afternoon, August 5, was actually printed in London on Thursday, August 4, and sent to Cambridge on Friday morning, when it was read by the audience assembled to hear the address. Various explanations have been offered as to the mechanism by which this feat was accomplished, and some have supposed that the difference in longitude between Cambridge and London, and the known fact that the electric telegraph travels more quickly than the earth revolves round its axis, may explain the mystery ; but this solution of the problem is not satisfactory to our own minds. We understand that it is probable the question, owing to its great intricacy, will be proposed to the candidates at the next examination for the Mathematical Tripos.

THE MURDEROUS ASSAULT ON DR. ROWE.—At the assizes held at Liverpool yesterday-week, James Potts Brice and James Scott were tried for the savage assault committed by them on Dr. Rowe. They were found guilty and sentenced to eighteen months' hard labour.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Mr. I. B. BROWN continues his "Clinical Lectures on the Diseases of Women remediable by Operation." In the present discourse he treats of Retroversion, Retroflexion, and Anteflexion of the Uterus. The first is the most common, and the third the most rare, kind of displacement. Retroversion may generally be rectified by position, by manipulation, and by keeping the urine evacuated by the catheter ; but retroflexion, according to Mr. Brown, sometimes requires for its cure that incisions should be made in the os and cervix uteri.——Dr. MURCHISON continues his "Contributions to the Etiology, Pathology, and Treatment of Scarlet Fever," his present subject being the exciting causes of the disease. He shows, what is indeed generally acknowledged, that scarlatina is caused by a peculiar poison capable of being communicated by the sick to persons in health. Dr. Murchison also shows that the period of incubation of scarlet fever is very variable, and its limits are from a few minutes to five days, though it rarely, if ever, exceeds six days.——Mr. F. H. ALDERSON gives a report of a "Case of Diphtheria, followed by Idiopathic Tetanus," the mouth being closed for twenty-four days, but the patient ultimately recovering. The case presents several points of interest, among which may be mentioned the fact that the attack seemed to be traceable to the patient having nursed some children suffering from malignant scarlatina. The treatment consisted in the administration of brandy and nutritious aliment, of croton oil given by the mouth, and of blisters locally applied.—Dr. F. H. MORRIS, under the head of "Contributions to Practical Medicine and Surgery," contributes a short paper on "Iodide of Potassium as an Antilactescent." The case on which the paper is founded was that of a female who lost her child a few days after birth, and in whom the iodide arrested the secretion of milk.

PARISIAN MEDICAL NEWS.

SUTURE OF THE MEDIAN NERVE.

M. Laugier recently communicated to the French Academy of Sciences some interesting particulars he had noticed at the Hôtel-Dieu, in a case of serious injury of the fore-arm.

The radial and ulnar arteries, the palmaris brevis and longus, a portion of the flexor digitorum sublimis, and the median nerve, had been completely cut across. The hæmorrhage being considerable, M. Ledentu, the interne of the ward, immediately secured both arteries, but failed in discovering the superior division of the nerve in the wound, and closed the latter with three separate sutures ; the hand was then laid on a cushion in semi-flexion. The hæmorrhage was thus checked, but next morning M. Laugier had no difficulty in detecting the effects of the entire division of the median, and of the partial section of the radial nerves. The Professor's attention was especially arrested by the loss of the movements of opposition of the thumb, and of sensation in the parts to which the median is distributed ; and he conceived that, in order not to throw away the chance of restoring both to the patient, it was desirable to connect without delay both ends of the nerve by means of a suture. The wound was accordingly re-opened, and the hand was placed in extension ; the inferior segment of the nerve was

immediately visible, protruding about one inch above the annular ligament, but the superior extremity had been drawn upwards with the fibres of the flexor sublimis. After short but unavailing attempts to recover it, M. Laugier found it impossible to expose the nerve without an excision. Chloroform was therefore at once exhibited, and the flap was divided vertically in its middle, on the anterior aspect of the fore-arm, in an extent of rather more than two inches. The flexor sublimis was incised, and the trunk of the nerve became apparent, and a silk thread was inserted through it with a nearly straight needle. The thread was then run through the upper extremity of the lower segment of the median nerve, and the ligature was tightened so as to bring into contact without violence the nervous surfaces; one of the ends of the thread was cut away, and the other was allowed to lie in the inner angle of the external wound.

The results of the operation were perfectly satisfactory. It was formerly believed that sutures applied to divided nerves occasioned excessive pain, and gave rise to formidable complications, such as tetanus. Nothing of the kind was observed in the present case. With regard to the restoration of the movements and of sensation, we may briefly state that on the very evening after the operation the patient was enabled to feel—indistinctly, it is true—the contact of objects applied over the previously paralysed surfaces. The next day the return of sensation was more evident, and the thumb was readily brought into opposition with the other fingers. The case has since progressed rapidly, and presents several points of much interest to the physiologist.

Already, on a former occasion, alluded to by M. Laugier, M. Nélaton performed the same operation with success, in a case of neuroma of the median nerve. After the excision of the tumour, and the removal of about ten lines of the nervous trunk, the surgeon united both ends with a metallic ligature, and in the course of forty-three hours sensation and motion began to return, and no accident supervened to retard the recovery.

These practical facts supply us, therefore, with full confirmation of M. Flourens' valuable experiment on the possibility of restoring motion and sensation, by uniting the divided extremities of a severed nerve. They further teach, as M. Velpeau remarked, that the return of the functions is very rapid—a circumstance which demonstrates, in opposition to the views entertained by some authors, that the restoration of sensation and motion is due to the direct apposition of the divided nervous tubes, and not to any indirect transmission of nervous power through other channels.—'Journal of Practical Medicine and Surgery.'

THORACENTESIS.

The Medical Society of the Hospitals of Paris lately engaged in a long and somewhat confused debate on the subject of thoracentesis; at its conclusion, M. Béhier summarised the various opinions expressed in an analytical review, of which the following is a brief abstract:—

"The surgeon is justified in proposing and performing thoracentesis," said M. Béhier, "whenever a very considerable effusion within the chest proves refractory to the usual remedies, and *à fortiori* if it increases;

"Whenever the patient appears too weak to bear the protracted effort of Nature to procure the absorption of an effusion occupying the whole or nearly the whole of one side of the chest;

"Whenever, in cases of a moderately abundant effusion, the lung presents on the opposite side a morbid condition calculated to add to the difficulty of breathing—such, for instance, as bronchitis, a certain amount of œdema, &c.;

"Whenever the subject seems predisposed to tuberculosis, no physical signs of such predisposition being discoverable, or even when positive proof of tubercular disease is afforded by auscultation on either side of the chest. If clear evidence of the presence of tubercles is detected in that side of the chest which is not the seat of the pleuritic effusion, the chances of success of the operation are, however, much less numerous.—'Journal of Practical Medicine and Surgery.'

ARMY MEDICAL DEPARTMENT.

The Director-General of the Army Medical Department presents his compliments to the Editor of the Medical Circular, and begs to enclose a list of the candidates who were successful at the Competitive Examinations in February and March last, and who have passed through a course at the Army Medical School, showing the combined results of the examination.

EXAMINATION AT THE CLOSE OF THE EIGHTH SESSION OF THE ARMY MEDICAL SCHOOL, ROYAL VICTORIA HOSPITAL, NETLEY, BETWEEN JULY 26TH AND AUGUST 3RD, 1864.

A. Written Questions.

(1.) *Military Surgery.* (Professor T. Longmore, Deputy Inspector-General.)

1. Mention the several purposes for which the convex and concave spectacles are supplied in the regimental optical and ophthalmoscopic case of instruments, and describe the method of using them, in conjunction with the test types for distinguishing emmetropia, myopia, hypermetropia, whether simple or complicated with presbyopia or amblyopia. Explain the theory on which the diagnosis in each instance is established.

2. Describe the nature, effects, and proper treatment of osteo myelitis after gunshot injuries of long bones, or of amputations consequent upon them.

3. Describe accurately, step by step, the operations of excising the shoulder and elbow-joints, each by a single linear excision, as practised in the post-mortem room.

(2.) *Military Medicine.* (Professor W. C. Maclean, M.D., Deputy Inspector-General.)

1. From what date may cholera be said to have engrafted itself on the epidemics of the soil of India? What are the conditions which appear to act most powerfully as predis-

posing causes of the disease? What influence do high or low situations respectively exert—

(*a*) On the proportionate mortality of those attacked?

(*b*) On the proportionate number of those seized?

Explain in what way excessively long marches appear to increase the virulence of an epidemic of this disease in soldiers, native or European, in India. Give an accurate description of the premonitory and actual symptoms

(*a*) In the slight,

(*b*) In the severe forms of the disease,

and describe the effects of its presence on the blood and secretions. What are the chief points to keep in view in our endeavour to exclude this disease from garrisons, camps, and cantonments, and to mitigate the severity of an epidemic when it appears? Give a description of the most rational treatment

(*a*) In the premonitory,

(*b*) In the confirmed,

(*c*) In the state of febrile reaction,

particularly stating in what stage and to what extent opium is safe.

2. What is the average weight of the liver, in health, in a man between the ages of eighteen and forty? Describe accurately its normal position and limits; explain the most common causes of abnormal position of the gland; give the precautions necessary to accuracy in the use of percussion and palpation in investigating hepatic diseases.

3. Give as complete an account as you can of the therapeutic uses and value of ipecacuanha in tropical medicine.

(3.) *Military Hygiene.* (Professor E. A. Parkes, M.D., F.R.S.)

1. What are the chief causes and effects of impurity of air in the habitations of men?

2. How would you determine the amount of carbonic acid, watery vapour, and suspended matters in the air?

3. Enumerate the principal adulterations of wheat flour, and state how you would determine—

(*a*) The quality of the flour;

(*b*) The presence of pea flour, oats, and maize.

4. What has been the Medical history of the West Indies as far as Europeans are concerned? State explicitly what you would do in a West Indian Station, if there occurred—

(*a*) A considerable number of diarrhœal and dysenteric cases;

(*b*) A considerable number of admissions from typhoid fever;

(*c*) A number of admissions from paroxysmal fever;

(*d*) Occasional outbreaks of yellow fever.

(3.) *Pathology.* (Professor W. Aitken, M.D.)

1. Give a classified account of the lesions in the kidney which were demonstrated during the past session in the practical room.

2. Describe the nature and probable origin of the parasitic cyst in the liver which proved fatal in the case of Private ——, as shown at the post-mortem examination of June 28th, 1864.

3. Mention the period of incubation, and describe the course and progress of an infecting venereal sore; and contrast your account with similar details relative to venereal sores which do not infect the system.

B. PRACTICAL EXAMINATION.

(1.) *Military Surgery* and

(2.) *Military Medicine.*

Make an examination of the case of ——. Write concisely a history of the case, your diagnosis, prognosis, the probable effects of treatment, and the influence of the disease, or injury, on the man's fitness for service as a soldier.

(Twenty minutes allowed for the examination; half an hour for the description.)

(3.) *Hygiene.*

Examination of two specimens of water;

Examination of adulterated milk and adulterated beer;

Microscopic examination of adulterated wheat flour.

(4.) *Pathology.*

Description of various preparations and microscopic specimens, and examination of secretions.

MEETING OF THE BRITISH MEDICAL ASSOCIATION AT CAMBRIDGE.

DR. ORMEROD ON FATTY DEGENERATION OF THE HEART.

The following are the remarks on "Fatty Degeneration of the Heart," made by Dr. Ormerod in his Address on Medicine, and which we were compelled to postpone last week from want of space:—

"It has been said that the decomposition of muscular tissue may be so regulated that the ultimate result shall be fatty matter; and it has been suggested that the transformation which takes place in the living body is the same as that which we can induce artificially by these means: in fact, that fatty degeneration is a physical, and not a physiological or pathological process.

"The experiments conducted for me by Mr. J. Peel, with all conceivable exactness, have not justified this view. I subjoin an account of these experiments in detail; for the present I will merely recapitulate the results at which we have arrived, and which seem incompatible with any purely chemical theory of fatty degeneration.

"We found the excess of fatty matter in a fatty heart to consist of oleine, not of margarine, which is the normal fatty constituent of the human heart. Adipocere was proved to be by no means chemically identical with animal substance which had undergone fatty degeneration. It was merely a soap of lime combined with the fatty acids pre-existing in the tissue. There was no new fatty acid made—as is the case in fatty degeneration—during the change into adipocere, no substitution of oleates for margarates; and, indeed, it seemed that we could prevent the formation of adipocere altogether by carefully excluding lime during the process. We submitted weighed portions of muscle, in which the quantity of fatty matter had been previously determined, to more than one process for making adipocere, and carefully analysed the results. In no instance was the fatty matter found to have been increased during the operation. On these grounds I cannot doubt that adipocerous transformation is a saponification, not a degeneration, and that fatty degeneration of the heart is a pathological result not attainable by any of these chemical processes.

"Commencing decomposition simulates very closely that change in the heart's muscular structure which is known as the first or granular stage of fatty degeneration. I have been deceived by it myself; and such a mistake is all the more likely to occur, because granular degeneration, like decomposition, may involve the heart uniformly over a very wide extent; much more widely than distinct fatty degeneration ever does, probably because the destruction of the muscular fibres is less complete. This same uniform appearance of granular degeneration is also highly characteristic of the effects of maceration in dilute spirit, on the muscular structure of the heart; but it is not really fatty degeneration. Ether only clears these fibres of some of the granular dottings, it does not entirely remove this appearance; still less does it empty the sarcolemma. Further, chemical analysis of a portion of heart which has undergone this granular degeneration during life shows but a slight increase in the normal quantity of fatty matter. This change is the first step, both in the chemical transformation into adipocere, and in the pathological replacement of the muscular fibre by oily matter; but it is not itself fatty degeneration. These dots are not oil globules, but the signs either of an integral change, on which fatty degeneration is subsequently engrafted; or, if so it should be, of commencing decomposition.

"The general conditions with which fatty degeneration of the heart is found to coincide are, for the most part, those with which we connect muscular atrophy and fatty degeneration of other organs. Such are phthisis, hæmorrhage, debility, from long mental or bodily suffering, and the effects of indolence or intemperance. The cases, however, with which we are here chiefly concerned are those when

the heart does not so much share in the general decay, as the decay begins at the heart, where the wheel is broken at the very cistern, as it were. Sometimes, while all the functions are regularly performed, the heart alone of all the organs is undergoing this fatal change; and the first intimation than anything has been going wrong is the sudden death of a seemingly healthy man. A gradually accumulating experience has, indeed, given us some general grounds for conjecturing the existence of fatty degeneration of the heart during life; and sudden death from this cause rarely comes altogether without warning. Still the fact remains, that in this decay the heart will often outstrip all the other organs, and will fail from a form of disease against which one would have thought that its own functions, its own constant activity, were the best preservatives.

"We are not in a position to say precisely what is the cause of this peculiar change originating in the heart's structure. We know, indeed, that the heart is liable to undergo fatty degeneration in consequence of inflammation extending inwards from the pericardium; but such an occurrence is rare. Indeed, the habitual absence of all traces of inflammation of the lining membrane of the heart, in cases of fatty degeneration—recollecting that this disease, as a rule, extends from within outwards—negatives the idea of inflammation, in the common acceptation of the word, being its habitual cause.

"Yet we cannot entirely dismiss the idea of inflammation as a cause of fatty degeneration of the heart, though the process which leads to this result has little in common with that which we familiarly know as tending to the exudation of coagulable lymph or pus. The aneurismal pouches which we find in the ventricles seem to originate in such a process. We see only the ultimate results over the prominent part of the sac; but at the edges, where it adjoins the healthy muscular tissue, we gain some insight into the nature of the process by which these results are reached. And here the zone of intense congestion points to excessive vascular action, to give it no more exact name, as the cause of this change of structure. One such case occurred in a girl, fifteen years of age, who had been ill only one month, and had suffered from heart symptoms during only a fortnight. And here the congestion was most intense at the line of union of the diseased and healthy tissues. Whatever share, however, this excessive vascular action may have in the process, the real analogies of acute fatty degeneration of the heart are to be found, not in inflammation of any organ, but in yellow atrophy of the brain and yellow atrophy of the liver,—both essentially acute fatty degenerations.

"Perhaps few pathological principles have met with more prompt and general acceptance than fatty degeneration of the heart in all its bearings; for, while it offered a sufficient explanation of much that had before seemed perplexing, it contradicted no known and established doctrines. Subsequent clinical experience has confirmed and extended the earlier deductions, and extends them still; and if yet there is a feeling of disappointment because angina pectoris has not received a full explanation from our present knowledge of fatty degeneration of the heart, is not this partly because cases of angina pectoris have seemingly become more rare, from the greater precision which the knowledge of this anatomical change has introduced into the nomenclature of cardiac disease?"

REPORT OF THE PROVIDENT FUND COMMITTEE.

We last week briefly reported the proceedings at Cambridge on the subject of the proposed Provident Fund, and we now print the Report of the Committee appointed last year at Bristol.

Dr. Richardson, as Chairman of the Committee, read the report, of which the following is a copy:—

"The Provident or Relief Fund Committee was appointed last year at the Bristol meeting, to consider and report on the question whether it be possible to establish, under the direction of the Association, a relief fund, which shall enable the widows of members, or the orphans of members, or members themselves, during sickness to receive pecuniary aid by annuity or otherwise, on the principle of mutual protection and right.

"The Committee have to report that their first meeting was held at Birmingham, the second in London, and the third at Cambridge. A sub-committee was also appointed by the first meeting, and has been actively engaged.

"The Committee has aimed at the attainment of two objects—first, to procure trustworthy information on the whole subject; and secondly, to frame such suggestions as appear, after due inquiry, to arise out of the facts that have been collected.

"Before entering into particulars, the Committee would briefly observe that in the course of their labours they were for a moment interrupted by the suggestion that an enlarged annuity scheme in extension of that which became law during the last session of Parliament would probably be introduced at an early period by the Chancellor of the Exchequer. The Chairman of the Committee was, therefore, directed to ascertain, if possible, whether this statement was well founded; and he has been informed by Mr. Gladstone that 'the Government have not formed any such intention as that referred to.' This supposed obstacle is, therefore, removed.

"The Committee would next report that, owing to the difficulties of arriving at a correct decision by their own efforts, it was agreed at their first meeting, on the suggestion of Sir Charles Hastings, that the sub-committee, consisting of the Chairman and Dr. A. P. Stewart, should consult Mr. Tidd Pratt, and take his opinion on every essential point of the project. This has been effectively done; and upon the information thus obtained the following statements are based:—

FACTS.

"1. The Committee are satisfied that, in considering a scheme for the formation of a relief fund, it is essential that two of the elements suggested at the Bristol meeting—namely, the granting of annuities and the making provisions for widows and orphans—must be entirely abandoned, and that the fund must be devoted exclusively to payments to sick members. Deferred annuities are now so easily purchaseable from Government, and insurances are so readily effected with good offices, that this decision of the Committee calls for no regret.

"2. By directing the attention of the Association solely to one object, there is no doubt whatever that a provision against sickness could be easily and economically secured; and the Association, through its branches, affords an organisation admirably adapted for obtaining these benefits.

"3. The number of members necessary to give stability to such a fund must not be less, according to Mr. Pratt, than 200. He states that '200 would be sufficient to enable the fund to start with a sufficient average.' This is the lowest estimate. But the Committee do not doubt that, the scheme being once established, a sufficient number of members would be obtained to ensure its permanence. It is, of course, understood that the fund would only be joined by persons actually in good health.

"4. The payments must necessarily vary with the age at which the subscriber commences his membership; but the Committee have taken the age of thirty-five for the purpose of illustration. They have also taken a payment of 2*l.* a week for the same purpose. They find that, at the age of thirty-five, the two pounds a week can be secured by the payment of 17s. 1d. per quarter, or 3*l.* 8s. 4d. per year. To this must be added a small sum of from 3s. to 5s. per year, for the working expenses of the institution. The payment would be continued, in case of need, for one year without diminution, and for a second year at a reduction of one-half. It would, in any case, terminate at the age of sixty. These statements are based upon the experience of fifteen successful institutions; and may be considered as absolutely reliable. If larger payments are wished for, they may be made by multiplying the above figures. It would be necessary that members should contribute for one year before they became entitled to relief.

"5. In forming a provident fund in connection with the

Association, three modes of action present themselves, namely—

"α. By enrolment under the Friendly Societies' Act.

"β. By independent association without special legal sanction.

"γ. By obtaining a royal charter of incorporation.

"The first of these is objectionable, because it would necessitate the enrolment of each separate Branch as a distinct society without any federal centre.

"The second plan, or independent association without legal sanction, is perfectly feasible; but the proceedings would rest entirely on the good faith of the members and the management. The Committee feel, however, that the organisation might safely commence on this basis.

"The third plan, that of obtaining a royal charter of incorporation, is, in the opinion of the Committee, by far the best. It would place the association in a position that it has never before attained; it would give legal authority to all its statutes; it would render the relief fund permanent; and would powerfully contribute to the stability of the Association. Mr. Pratt is of opinion that, on the basis of the Provident Scheme, the charter would be easily obtained; and he has sketched out for the Committee the method of applying for it. The Committee find that such a charter would cost from 250*l.* to 300*l.*

SUGGESTIONS.

"1. The Committee would suggest that the Relief Fund might be commenced forthwith, from the nominal date of July 1st last past, and that the subscribers should be eligible to receive benefit from July 1, 1865, after payment of their second annual subscription.

"2. That, in order to carry out the project, a board of directors should be nominated in the following manner, to wit:—

"One director to be appointed by the members or Council of every branch; or, in the case of very large branches, two, or even three, directors in proportion to the numerical strength.

"Three, or five, directors to be appointed by the Committee of Council on account of members not represented by branches.

"A chairman to be elected by the annual meeting from the body of the Association.

"The directorate thus formed have power to appoint their own officers, and to determine their remuneration. They would furnish, also, the annual report at the time of the annual meeting.

"3. A question which has given anxiety to the Committee is, whether the Relief Fund should be open to the Profession generally, or should be limited to the members of the Association. A large majority of the Committee are in favour of the latter scheme, against which it is only urged that membership of the Association being of the nature of a luxury ought not to be a condition precedent to an act of foresight and self-denial."

At this stage of the report the Chairman read the following protest from one of the members of the Committee:—

"Stroud, August 3, 1864.

"The undersigned is desirous to call the attention of the Association to the question, Whether the proposed Provident Fund would be open to the Profession generally or to members of the Association only?

"Upon reflection, the undersigned feels more and more strongly that its limitation to members of the Association would be a great and unjustifiable hardship to many struggling men. Such a limitation might, as is justly urged by the majority of the Committee, bring new members into the Association; but would it not certainly keep others, and those the most necessitous (for whom their more fortunate brethren are surely bound to take thought), from sharing in the benefits of the provident scheme?

"The undersigned begs leave to suggest that the Association might include two forms of membership—membership of the provident fund and membership of the general fund, and that it should not be compulsory to belong to both or neither. He is strongly of opinion that men who joined the provident fund would be certain to join the general fund when their means permitted them to do so; and he would venture to hope that the great majority of members of the general fund would support the provident fund also. But he would much regret that the tax of an extra guinea should stand in the way of any practitioner of small means who yet wished to secure himself against want in the time of sickness.

"ROBERT B. CARTER, F.R.C.S."

"4. Another question of importance is whether the sick members during convalescence should be absolutely debarred from any act of professional work. On this point, Mr. Pratt is of opinion that 'no member should receive relief in sickness from the fund if he is capable of attending to any professional labour;' but the Committee think that this question may be safely left to the patients, and to those who sign certificates for them, and that such certificates should declare *unfitness* for work, rather than positive disability. This, as a matter of detail, the Committee would leave with the directorate.

"5. The Committee have reason to believe that, if the fund were established, donations and legacies would be added to it; but all the calculations have been made irrespectively of such a source of income.

"6. To meet preliminary expenses, should the Association adopt the report of the Committee, a moderate grant from the funds would be required. The Committee would suggest a sum of 50*l.* to be paid by the Treasurer as it was demanded.

"6. It would devolve upon the board of directors to prepare detailed rules and bye-laws as soon as possible, and to circulate them extensively in the Profession.

"8. In conclusion, the Committee cannot too strongly urge the importance of the suggested Royal Charter of Incorporation; the obtaining of which by the Association would greatly strengthen the cause they have at heart.

"Signed on behalf of the Committee,

"B. W. RICHARDSON, M.A., M.D.,

"Cambridge, August 3, 1864. Chairman."

As we formerly stated, the report was adopted after some discussion, the particulars of which will be found in our pages of last week.

GENERAL CORRESPONDENCE.

MEDICAL EDUCATION.

To the Editor of the Medical Circular.

SIR,—The hints on Medical Education thrown out by the Archbishop of York at the late distribution of prizes at St. Mary's Hospital Medical School are so replete with sound judgment, and strike so truly at many of the defects in our Medical education, that I cannot forbear offering a few remarks on the subject, in confirmation of the opinions propounded by his Grace.

As a general rule, it is but seldom that those who hold the high position of teachers in any branch of education can see the defects that exist in it.

When abuses are to be remedied in the Church, Army, or Navy, do we find that the impulse for the removal of those abuses takes its rise from those engaged in those professions?

The education of the embryo practitioner, to whom will be committed the life of his fellow-man, is not to be lightly dealt with. It is a subject to be solemnly approached, and not to be tossed about by "every wind of doctrine."

It is a subject on which the success of a Medical man's future career may depend. It is also one by which a Medical man may be able to sustain a position once acquired, and it appears to me that the Archbishop has done much for inculcating the proper mode of impressing on the minds of students the sentiments emanating from lecturers.

Now, Sir, in what respect does Medical education differ from education in other branches of knowledge? How few Medical students are there who are impressed more than students in other branches of knowledge with the necessity of

deeply meditating on every word spoken by the lecturer? How few are there whose capabilities enable them to keep up an uninterrupted attention for one hour without a pause? And, Sir, it is not for one hour, it may be for six or seven hours, I was going to say, almost consecutively.

Let me for a few moments survey the daily routine of a Medical student's career at the age of eighteen or twenty years, and tell me if it is such that his mental faculties can be improved by such wear and tear of his physical system. He is sent, it may be from the bosom of his family, or it may be from school, where he has had, at least, good air, into a city surrounded by, and exposed to, all the temptations of youth. His mornings are passed in an hospital, the air of which must be impregnated with the exhalations of disease, be it surgical or medical. His visit to the patients over, he is transported to the dead-room, there to witness the examination of disease to which the anxious student may have been devoting his attention. From thence he goes to breakfast, which finished, he may speed with all the energy of an anxious mind, to be found for an hour or more, it may be, at the dissecting-table, previous to the commencement of lectures. Come with me now into the lecture-room. The benches are gradually filling as the hour for the lecture approaches. The lecturer enters the arena. The hum of salutations ceases. Note books, it may be, are produced. Pencils are cut, and all the precursory steps for taking notes are finished. The lecturer begins. His watch lies on the table. "Gentlemen, the subject of our lecture yesterday brought us down to 'so and so.'" The lecture may be highly intellectual, truthful, and correct; he reads from notes, or it may be a written lecture of former years. The subject may be an abstruse one, and one requiring repeated explanation and commentary. It may be one in which the latest and most obscure discoveries of Medical science may be promulgated, for the elucidation of which the learned professor may have passed many anxious hours and even wakeful nights, or it may be that he has strung many sentences together, without regard to their import or connexion. The willing student writes a few lines; the lecturer has, however, got in advance of him, and when the student has finished his sentence, he finds that the lecturer's next bears but little connexion with the one which he has written; and so, with frequent interruptions, the anxious student at the end of the lecture can make but little out of what he has heard, having lost more than half of what the learned professor has been expounding. But let us turn for one moment to another class of student, who sits, it may be, with demure aspect, alternated by an occasional smile which creeps over his face. He has been thinking, perhaps, of home—it may be of the amusements which he has so much enjoyed there, it may be of the revellings of the past night, it may be of some peculiarity in the speaker, or perhaps of anything rather than the lecture, trusting to books to gain the information which thus is being thrown away. So hour after hour is passed, unprofitably to the student, and a burlesque to lectures.

Let us take an example of another class of students, probably the smaller, who prefer trusting to memory for the information gleaned from lectures, rather than noting the same in his book. Of this class let us take one; see his blood contaminated by noxious effluvias, his strength tried by night watches, and "whose candle goes not out by night" in endeavours to keep himself acquainted with what he has heard by day. Observe his anxious and tired look when he endeavours to absorb into an already overwrought brain the varied studies of a Medical career. Can it be wondered at that the "passive attention" so aptly described by the Archbishop of York is in the majority of cases not attention at all.

I have for many years taken an interest in this subject, and in private letters to my Medical friends have often brought before them the mode of instruction which I have witnessed in Italy. To take, for example, the Medical school at Pisa, which has had for many years a great reputation. The professor enters the lecture-room, the roll of students is called. He then questions the student on the subject of the previous day's lecture; the diffident he encourages, the student of moderate ability he assists. The well-read he stimulates by the remarks he makes on his well digested and accurate answers, the idle he reproves, and urges on all to put any questions that they wish to do on the subject of the previous day's lecture. This examination lasts generally ten or fifteen minutes. He then proceeds to the subject of the lecture for the day, of which he is master, and in well-considered language explains the matter of his discourse in a form comprehensible to the lowest order of minds before him, stopping at the end of every fifteen minutes to put various questions to the students on what he has been saying. In this manner, the flagging attention is kept alive, the student perceives that the intellect of the lecturer is keeping pace with his words, and a warm interest is encouraged in the subject of the lecture.

To carry out fully the ideas of the Archbishop, that the lecturer should see to the progress of the students at other times than during lecture hour, would doubtless be attended with difficulty on account of professional occupation, but during the time of the lecture no exertion should be omitted on the part of the lecturer to keep alive the attention of the student by diversifying the mode of imparting instruction.

In some Medical schools, the practice of examining the students once a week on the subject of the lectures has been attended by the very best results.

Doubtless the hints thrown out by the Archbishop will have their effect, and may be made the means of engraving many names in the memory of the public, rather than on the wooden benches, which is too much the practice among Medical students, who are frequently engaged cutting their names with their penknives on them, wholly inattentive to what is being said.—I am, &c.,

12 Via della Mercede, Rome, July 9, 1864. JOHN GASON, A.B. Fell. Coll. Phys., Irel., &c.

SUBSCRIPTIONS FOR THE WIDOW AND CHILDREN OF THE LATE EDGAR BULL, ESQ.

The Rev. H. Bromfield gratefully acknowledges the receipt of the following donations for the widow and children of the late Edgar Bull, Esq., Surgeon, of Blockley, and earnestly solicits further assistance:—

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members, having been elected Fellows of the College at previous meetings of the Council, were admitted as such on the 8th inst.:—Octavius Adolphus Field, Sussex gardens, Hyde park—diploma of Membership dated Aug. 12, 1836; Gerald Yeo, Royal Navy—diploma of Membership dated Dec. 24, 1841.

In the list published last week of gentlemen admitted as Members of the College on the 30th ult., the name "Bluvitt" should have been "Blewitt."

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 4th inst.:—Alex. Hampton Brewer, Victoria, Monmouthshire; George Alex. Augustus Coats, Sirhoury, Monmouthshire; John Hankinson Gornall, Royal Infirmary, Liverpool; Thomas Wimpenny Green, University of Glasgow; Arthur Hill, Cumberland street, Pimlico; Ernest Arthur Hudson, St. Mary's Hospital; Richard Hughes, Rectory, Llanddenioler, Carnarvon; William Parsons Knott, Blisworth, Northamptonshire; Joseph Langhorn, Brompton road; Frederick Lawton, Chiddingford, Surrey; Nynian Holman Lower, Lewes, Sussex; Edward Reynolds Ray, Dulwich, Surrey; Albert James Wallis, Cambridge; Charles White, Guy's Hospital; John Williams, Anglesea.

The following gentlemen also on the same day passed their first examination:—Charles Arthur Brigstocke, St. Bartholomew's; George Fowler, Guy's; Herbert Lucas, Guy's; Edward Alfred Trimnell, Guy's.

UNIVERSITY OF LONDON.—The following is a list of gentlemen who have passed the first M.B. examination:—*First Division.*—Francis Bateman, St. Bartholomew's; Stephen Wootton Bushell, Guy's; Thomas Cole, St. Bartholomew's; Henry Greenway Howse, Guy's; James Pearson Irvine, B.A., University College; Frederic Barham Nunneley, University College; Charles William Philpot, King's College; Thomas Claye Shaw, B.A., King's College; George Christopher Tayler, St. Bartholomew's; John Burges Welch, King's College.—*Second Division.*—Arthur Bayley Adams, London; John Augustus Ball, Guy's; Marcus Beck, University College; Charles Berrell, King's College; Other Windsor Berry, Charing cross; Francis John Buckell, University College; Henry Clothier, University College; George Eastes, Guy's; Charles Kelly, King's College; John Lloyd, Queen's College, Birmingham; Charles James Hardy Smith, University College; George Owthwaite Spencer, University College; Arthur Taylor, Guy's; Thos. Pickard Warren, Guy's; John Williams, University Coll.

EXCLUDING PHYSIOLOGY.—*First Division.*—John Pearson Hughes, University College. *Second Division.*—Henry Hargreaves Birtwell, St. Thomas's; Julian Augustus Michael Evans, University College; John Spencer Ferris, King's College; Ralph Gooding, B.A., King's College; John Grimes, King's College; John Wickham Legg, University College; George Hunt Orton, St. Bartholomew's.

THE ARMY MEDICAL SERVICE.—A memorial has been presented to Lord Palmerston by the Royal College of Surgeons of Edinburgh on the subject of the Army Medical Service. The memorial sets forth—"That it is obvious that that department is not in a satisfactory condition, there being, as the College have reason to believe, widespread discontent among the Army Medical Officers—the Medical Service of the Army having become so unpopular that medical men are repelled from it, instead of being attracted to it; and that there is found to be great difficulty in filling up vacancies as they occur, and that to an extent which seriously mars the efficiency of the service, and imperils the health of the army." After adverting to the expedients to which the War-office has had to resort, the memorial proceeds:—"That various reasons have been stated why the service should be at the present time so unpopular—such, for example, as that the excellent Warrant of 1858, which gave so much satisfaction when it was originally issued, has not been carried out as it ought to have been; that its operation has not been extended to India, as was due to Indian medical officers; that medical officers, in consequence of the deficiency in their numbers, have a difficulty in getting leave of absence have, an undue share of foreign service, and are very slowly promoted. That, moreover, they are slighted as regards rank, have degrading duties unnecessarily imposed upon them, and as regards pay and arrangements as to retiring pension, are not remunerated as is due to men belonging to a liberal and scientific profession, qualifications in which can be attained only after long years of study and at a great cost. That the College refrain from giving an opinion as to the relevancy of these alleged causes, believing as they do that the only satisfactory means of ascertaining the real causes and amount of the evil, and of applying the proper remedies, is the appointment of a Royal Commission to inquire into and report regarding the whole matter." The memorialists accordingly petition Lord Palmerston to advise Her Majesty to issue a commission, "constituted of men of weight and impartiality, in whose judgment confidence may be reposed by all concerned."

THE GUARDSMAN SHOT AT WIMBLEDON.—Private H. Cooper, of the Coldstream Guards, who was accidentally shot on the 21st ult. at Wimbledon, died there on Tuesday at six o'clock. He was making a favourable recovery as regards the wounded side until Friday night last, when symptoms of congestion of the lung on the sound side became evident. These gradually increased in intensity, and he sank without pain at the hour stated. At the inquest held on the body, Henry Cramer Guinness deposed,—I am Staff Assistant-Surgeon, and I had charge of the detachment of Guards stationed at Wimbledon during the late meeting. I was on duty on the afternoon of the 21st of July, and I was summoned to Thomas Cooper in the Volunteer surgeons' tent. There were several Volunteer surgeons present. I took charge of him then in conjunction with Dr. Westmacott, of the London Scottish. I found that the man was suffering from a gunshot wound in the chest, and was in a complete state of collapse. The ball had entered behind between the ninth and tenth ribs, and glanced upwards to the third and fourth. It had entered at the back, at about two inches from the spine. There was a bruised mark at about an inch and a half above the nipple. The bullet was in his body. From that day the man was under my charge, in conjunction with Surgeon-Major Wyatt, and he progressed favourably until last Friday night, when congestion of the right lung set in. From that time to the time of his death, which happened on Tuesday morning, he was in an alarming condition. I made a *post-mortem*, in conjunction with Surgeon-Major Wyatt, and I found the ball produced. [The ball was shown. It was the common Enfield, and was flattened at the point.] It was lying loose against the diaphragm where the diaphragm is attached to the spine. I traced the wound from the external orifice into the lung. The ball had passed through the muscles and through the lower lobe of the left lung, and had lodged between the third and fourth ribs on the left. The man died from congestion of the right lung, and his death decidedly arose from the injury he received. The ball is a rifle ball, and it is flattened by going through three inches of board backing.

POISONING BY CALABAR BEANS.—About one o'clock on Thursday last the greatest excitement prevailed in the neighbourhood of Parliament street and Greenland street, Liverpool, in consequence of a rumour being prevalent that upwards of sixty children had been poisoned by eating some obnoxious beans. Unfortunately, the rumour proved to be too well founded. It appears that between one and two o'clock a little girl named Mary Ann Foster was taken to the Southern Hospital by some women. The child was in great suffering, and the surgeons of the hospital were informed that she had been eating some beans which she had gathered from a heap of rubbish thrown from a cart on some vacant land in Greenland street. Dr. Cameron, and Drs. Wollaston and Evans, the resident house surgeons, immediately attended the child; but before they had time to administer the remedies considered necessary for her about twenty other persons arrived with children in their arms suffering in a similar way. The medical gentlemen, seeing that

the case was an urgent one, and that the children were evidently suffering from a narcotic irritant poison, brought into requisition the whole resources of the institution, and antidotes were applied to counteract the effects of the deleterious stuff which the children had taken. The operating-room at this time presented a heartrending appearance. The poor children seemed to be suffering acutely from pain, and many of them were retching violently, while their mothers or friends were crying most piteously. From one to half-past three o'clock about forty children were taken to the hospital. One of them, who resided with his parents in New Bird street, died about ten minutes after he was admitted, although all means were taken to save him. This is the only case, up to the present, where fatal results have occurred, but several of the children are not, by any means, out of danger. The consequences would, no doubt, have been much more serious had it not been for the prompt medical assistance that the children obtained. The remedies applied were the stomach pump, emetics, stimulants, &c. The symptoms which the children exhibited were somewhat peculiar, although they clearly showed the sufferers had taken some poison of a deadly nature. The children were pale, very sick, and exhausted, and when they attempted to walk they staggered about as if they were drunk, although they had the use of all their senses, the poison which they had taken evidently not producing that stupefying effect which results from the taking of opium. Their pulsation was at first very low; some of them became feverish and drowsy, and their eyes were bright and protruding from the sockets, and in some of the worst cases the pupil of the eye was contracted. The quantity of the beans which the children stated they had eaten produced somewhat different effects. In one case, where a girl had eaten twelve, her recovery was easily accomplished; whereas in the case of another child, who stated that she had only eaten two beans, it was for some time feared that fatal results would follow. The child who died ate, it is stated, only six of the beans. From inquiries made by the police as to how the children got the beans, it appears that about eleven o'clock in the forenoon a cart, belonging to some person at present unknown, deposited a lot of rubbish on some vacant ground belonging to the Corporation, adjoining the schools connected with Great George street Chapel, in Greenland street. Some of the children began to scrape among the rubbish, and found a quantity of large oily-looking beans. The little things, in their ignorance, ate some of the beans, as they had not an unpleasant taste. The news of the discovery quickly spread among the children in the locality, whose parents generally belonged to the poorest class, and a number joined in the search and partook of the beans, with the results already stated. The police-inspectors, hearing of the occurrence, ordered the rubbish on the ground to be taken charge of by a number of policemen. Subsequently they caused it to be riddled, when upwards of a bushel of the beans was obtained. The master of St. Barnabas School, which is close by, also took a large quantity of beans from some of the children attending the school. The bean found is known by the name of *physostygma venenosum*, or "Calabar bean," is said to be used for dyeing and tanning purposes, and is a deadly poison. The rubbish from which it was obtained in so large a quantity by the unfortunate children is said by some to be ship sweepings and ballast taken from a vessel just arrived from the West Coast of Africa, while by others it is alleged to be the sweepings of a warehouse floor; but, from the nature and appearance of the rubbish, the former seems to be the most likely supposition.

APPOINTMENTS FOR THE WEEK.

Wednesday, August 17.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, Caledonian road, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

Thursday, August 18.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Friday, August 19.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, August 20.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

Monday, August 22.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

Tuesday, August 23.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Board of Works, Holborn District, Fifth Annual Report of the Medical Officer of Health.

Journal de Médecine Mentale, No. 7. July, 1864.

The Social Science Review, No. VIII., New Series.

The Canada Lancet, No. 17.

Photographs (coloured from Life) of the Diseases of the Skin. By A. B. Squire, M.B. Lond., &c. No. 1. London: John Churchill and Sons, New Burlington street.

The Chemical News, 242 and 243.

The Pharmaceutical Journal, Vol. VI., No. II.

The Dublin Quarterly Journal, No. LXXV.

The Canada Medical Journal, No. 2.

Metamorphoses of Man and the Lower Animals. By A. De Quatrefages, Paris; translated by Henry Lawson, M.D., &c. London: R. Hardwicke, 192 Piccadilly.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

The Rev. H. Bromfield's letter is inserted.

Castleton, *Yorkshire*.—The L.F.P.S. Glasgow is equivalent to the diploma of a College of Surgeons, and we believe that the L.R.C.P. Edin. is equivalent to a licence in Medicine, although it gives no right to the possessor to practise pharmacy in England and Wales.

The Griffin Testimonial Fund.

To the Editor of the Medical Circular.

Sir,—The following subscriptions have been further received on behalf of the above Fund:—

	£	s.	d.
Messrs. Clark and Elliott, Lynton	0	10	0
Ed. Hall, Ulverstone	0	10	0
Geo. Bulmer, Esq., Leeds	0	10	0
W. A. Burr, Esq., Slough	0	10	6
Thos. Robinson, Esq., Cheadle	0	2	6
Joseph Toynbee, Esq., Saville row	1	1	0
Francis Davies, Esq., Pershore	1	1	0
Amount previously announced	48	3	0
Received at 'Lancet' Office	3	11	0

Yours obediently,

Robert Fowler, M.D.,

145 Bishopsgate st. Without, Treas. and Hon. Sec.

August 10, 1864.

The Army Medical Department.—The list is published.

The University of Cambridge.—The paper from a member of this University shall appear next week.

A Surgeon of Volunteers.—Considerable want of Medical etiquette was exhibited in the case of the soldier Cooper who was unfortunately shot at Wimbledon. The case properly belonged to Mr. Wyatt, but Dr. Westmacott happened to be the first surgeon applied to, and very properly rendered his services until those of Mr. Wyatt could be obtained. The presence of Mr. Prescott Hewitt, although unnecessary, was caused by the zeal of some of the military authorities. We are decidedly of opinion that Dr. Westmacott ought to have been invited to the post-mortem examination.

A. B.—We have heard that the disease was delirium tremens, but we do not vouch for the fact.

Dr. Gason.—The subscription has been received.

A Subscriber.—The question is surrounded with considerable difficulty, but our impression is that the appointment was for a year, and that the Medical Officer, therefore, could not be dismissed before the expiration of that term.

Quæso.—The permanganate of potash is a powerful antiseptic, and may be used in the form of a gargle or lotion. It has, we believe, been used internally in the treatment of diabetes, but we do not know with what success.

BARTH'S OXYGEN WATER

HOLDS FREE OXYGEN IN SOLUTION,

gently stimulates the functional action of the stomach and secretory organs, and is a very pure useful beverage. WENTWORTH SCOTT'S Analysis gives as contents of a bottle—"Nearly half of an imperial pint of distilled water, and about 13·5 cubic inches, or 4·6 grains of gaseous oxygen; equivalent to that contained in 21·4 grains of chlorate of potash."—4s. per dozen.

OXYGENATED WATER COMPANY (LIMITED), 36 LONG ACRE.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

THE BEST HOUSE FOR SECOND-HAND INSTRUMENTS,

where there is the LARGEST STOCK IN LONDON, IS Mr. WILLIAM LAWLEY'S, 7S FARRINGDON STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each. Photographic Lenses, Opera and Race Glasses, Microscopes, Mathematical Instruments, and Telescopes, by Ross, Dollond, Voigtlander, Troughton, Simms Elliott, and other eminent makers.——Catalogues forwarded on receipt of Stamp.

BLOCKEY'S LONDON STOUT

NOURISHING LONDON STOUT

DR. HASSALL'S REPORT:—"I have carefully analyzed Blockey's well-known Stout, as obtained from 21 Duke street, St. James's, and find it to be a genuine, most wholesome, and highly nourishing beverage, less heavy, and consequently more digestible than London Stout in general.—Signed, ARTHUR HILL HASSALL, M.D London, Analyst of 'The Lancet' Sanitary Commission." Casks of 4½, 6, 9, and 18 gallons, at 1s. 8d. per gallon; 3s. per dozen pints; 5s. quarts. RAGGETT, late Blockey, 21 Duke st., St. James's. Established 100 years.

Pulvis Jacobi ver, Newbery

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

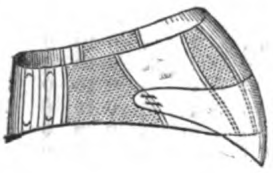
Prices for Dispensing—1 oz., 9s.; ½ oz., 3s. 4d.

MR. P. BOURJEAURD'S REGISTERED SPIRAL ELASTIC

BANDAGES, to be obtained only at No. 11 DAVIES STREET, BERKELEY SQUARE, W., and No. 49 RUE DES BEAUX-ARTS, PARIS.

Mr PHILIP BOURJEAURD, in submitting the accompanying diagrams, presents his best thanks to those Gentlemen who have, for some years past, prescribed his appliances in cases indicating their necessity, and begs respectively to assure others, who have not used them in their practice, that they will find them a most valuable assistance in most cases indicating their necessity of compression or support. The inventions consist of Abdominal Supporters, Hernia Apparatus, Ankle, Knee, and other Bandages, with various other Appliances, that the élite of the Profession have pronounced to be most ingenious.

N.B.—No. 49 DAVIES STREET, BERKELEY SQUARE, W., near Mivart's Hotel. The establishment is strictly private, not having any show of Bandages in the window. A highly-respectable married female to wait upon Ladies, who may insure her attendance in Davies street, or at their own establishments, by favouring Mr Bourjeaurd with instructions according to their own preference.—Poor Patients are supplied at a reduction of thirty per cent. lower than the imitations.



AT HOME FROM TEN TILL SIX.

J. & E. BRADSHAW,

LATE

SHOOLBRED AND BRADSHAW,

34 JERMYN STREET,

Beg to call attention to the various improvements in Patent ELASTIC STOCKINGS, BELT, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera and the cure of Rheumatism, Lumbago, &c.

*** Every description of INDIA-RUBBER BANDAGE, vulcanised on the newest principle. Directions for Measurement sent by post.

N.B.—A Liberal Discount to the Profession.—A Female to attend on Ladies.

T. Morson and Son are enabled to offer Pepsine (or Poudre Nutrimentive,

guaranteed to answer the test adopted by the IMPERIAL COMMISSION FOR THE PREPARATION OF THE NEW FRENCH CODEX, as follows:—Mix 20 grains of Pepsine with 1 oz. of water, acidulated with 2 drops of Hydrochloric Acid, and add 120 grains of Fibrine deprived of water by pressure between bibulous paper or folds of calico. After a lapse of some hours, the Fibrine should be partly in a state of pulp suspended at the bottom of the vessel. On filtering the syrupy solution, if the liquid gives no precipitate with 2 drops of Nitric Acid, the digestion may be considered efficient, and the Pepsine pure. During the operation a heat of 120° Fahr. should be maintained, but not exceeded.

PEPSINA PORCI. PEPSINE WINE.

19 AND 46 SOUTHAMPTON ROW, RUSSELL SQUARE.

Agents: Drew, arron, and Co.; Gale and Co.; Hodgkinson, Tonge, and Stead; B. Yates and Co

Kinahan's LL Whisky v. Cognac BRANDY.

This celebrated Old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, andvery wholesome. Sold in bottles, 3s. 8d. each, at most of the respectable retail houses in London; by the appointed agents in the principal towns in England; or, wholesale, at 8 Great Windmill street, Haymarket.—Observe the Red seal, pink label, and cork branded "Kinahan's LL Whisky."

Flour — (Essex) — Warranted free

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs.), 9s. 0d. Households (recommended for bread-making), 7s. 8d.; Seconds, 7s. 0d.; Wheat Meal for brown bread, 7s. 0d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

Dr. Arnott's Hydrostatic or Floating

BEDS FOR INVALIDS. Also Air and Water Mattrasses. For prices and particulars, apply to EDWARD SPENCER and Co., 87A Fenchurch street, London, E.C.

Bennett's Watches, 65 & 64 Cheap-

SIDE, in gold and silver, in great variety, of every construction and price, from 3 to 60 Guineas Every Watch skilfully examined, and its correct performance is guaranteed. Free and safe by post.

Money Orders to JOHN BENNETT, Watch Manufactory, 65 and 64 Cheapside, and 62 Cornhill, E.C.

Kamptulicon, Floor-cloth. — The

attention of the Medical Profession is requested to be given to the many advantages of this article as a floor covering, for the Wards of HOSPITALS, Surgeries, Nurseries, &c. It is non-absorbent, quiet, and warm to the tread, will not hold dust, is very easily and quickly cleaned and will stand any amount of hard wear. It has already been adopted in several hospitals.

GOUGH and BOYCE, 76 CANNON STREET WEST

Original Patentees and Manufacturers

Forwarded to all parts of the Country.

Microscopic Glass.—Thin Glass for

Mounting Objects, in squares or circles. Slides 3 in. by one in., and Cells of every kind, supplied Wholesale and Retail, by

CLAUDET and HOUGHTON, 89 High Holborn London.

N.B.—Aquariums, Fern Cases, and Glass Shades.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ORIGIN AND NATURE OF SYPHILIS.

By Richard Samuel Sisson, M.D.

(Continued from page 104.)

It appears to me that if, as we are told, hard and soft chancre are totally different diseases, it would be impossible for us to convert one into the other by any means we possess, and our experience in other diseases is opposed to such a theory; and consequently I believe the statements of Lee and De Meric go to prove that the hard and soft chancre are the same disease, but in a different state of activity.

Let us see if the results of syphilization bear out Professor Aitken's statement—viz., that it has been shown that the infecting sore is not inoculable upon the patient himself, nor upon a person who has been contaminated by syphilis.

Dr. Aitken thus describes the process :—

1. Matter is taken from a sore, *an indurated one by preference.*

2. *A patient suffering with secondary syphilis, is inoculated.*

3. From the pustule, which forms in about three days, fresh inoculations are made.

4. Every third or fourth day continue so to inoculate, always taking matter from the last pustule, so long as it continues to give any result.

5. When it ceases to give any result, new matter is to be sought for from another *primary indurated ulcer*, and continuous inoculations to be made as before on the sides of the person's body, and so on until no further inoculations will succeed.

It appears, then, if these rules are available and collected from reliable experiments, that not only is the infecting sore inoculable upon another syphilitic patient, but is also capable of auto-inoculation; for Ricord, Marston, and others have shown, that although inoculation from a hard chancre upon a syphilitic patient may produce a chancre with a soft base, yet the result of inoculation with matter from this sore upon a previously healthy individual will be an indurated chancre, which may be followed by constitutional symptoms; proving thereby that this soft sore is a truly infecting chancre.

Syphilis, says Professor Aitken, in course of time tends to wear itself out of the constitution. Hence the *modus operandi* of so called syphilization may be explained conjointly by—1. Lapse of time. 2. By continuous suppurations affording a drain or source of depuration to the system.

Now, this explanation appears to me unsatisfactory; for if the syphilitic poison was eliminated from the system, surely we should expect, not that the inoculations should at last fail, but that we should have the indurated chancre reproduced in all its pristine vigour.

Boeck holds syphilization not to be merely a local process, acting by derivation or by reparative suppuration, but to be analogous to vaccination ('New Syd. Soc. Year-Book,' 1860). And Marston, Seaton, and Simon have shown a constant relation to exist between the number of the sufficient cicatrices and the degree of protection afforded by vaccination. (Aitken's 'Pract. Med.')

By analogy, then, we must conclude that one attack of syphilis does not necessarily confer perfect immunity against another; and since it is stated, on the best authority, that the result of syphilization is the same from whatever kind of chancre the inoculations are made, we are, I think, driven to the conclusion that there is but one chancrous poison; and that the character of the sore is determined either by locality, or constitutional peculiarities. The first I infer from the statement of Ricord, that "he has never seen soft chancre on the face or cranium, though he has met with indurated chancres in hundreds in those situations; and the last, from the well-known fact that indurated chancre is rarely seen in women.

There is nothing remarkable in the fact that chancre contracted by a previously infected individual should put on an appearance different from what would occur in a healthy person. When one only partially protected by a previous attack of small-pox, or by vaccination, is subjected to infection, how is he affected? Not by a regular attack of variola, but by a modified form, in which the eruption stops at the papular or vesicular stage; nevertheless, in this state, he would communicate the genuine disease to another unprotected.

Moreover, as Professor Aitken has stated, nothing can be more different than the distinct, the confluent, and the horn small-pox from each other; and yet all these different varieties may exist in different persons inoculated with the same poison.

In treating of skin diseases, the same author remarks: "There are numerous facts which justify the belief that there exists but one essential fungus whose sporules find a soil for development and growth upon the surface, or even within more secluded portions of the human body; and that varieties in the growth of that fungus are due *to differencces in the constitution of the individual*, to the moisture, exudation, soil, and temperature under which the development of the fungus takes place." And again: "An amount of fungus which will simply produce death of hair in one person, or part of the body, may, in another, produce irritation, eruption, or violent inflammation."

Sir George Ballingall held that "the contagious principle does not always produce the same symptoms."

Dr. Hennen observed: "Soldiers are gregarious in their amours, and we have frequently several men in hospital at the same time, infected by the same woman, some of whom have had one kind of sore, some another, and some both."

Mr. Acton has known instances of a male with indurated ulcer communicating to a female a simple unindurated sore, and *vice versâ*.

"The inoculation," writes Mr. Paget, "of several persons with the matter from one primary syphilitic sore may produce different forms of the primary disease and different consecutive phenomena." And again: "I believe we must assume that the specific material of each disease may be, in some measure, modified by its combination with one or more of those normal materials of the blood, which have in each person a peculiar or personal character. By such combination we may best explain those characters of specific disease, which appear in its changes in transmission from one person to another; such as the varieties of syphilitic sore, and the varieties of their consequences, in different persons inoculated from the same source." ('Surgical Pathology.')

In Reg.-Gen. Report on Cholera, 1848-9, Dr. Farr observes: "Syphilis, erysipelas, and other zymotic diseases put on different forms, which may be referred to the state of the exciter, the mode of its application, the matter on which the exciter acts, or the vitality of the patient."

Boeck says: "There is but one syphilitic virus. The soft is produced by the same virus as the indurated chancre; the two forms arise from the intensity of this virus being different. Soft chancres are the product of the most energetic virus, which, by its intensity, developes in its circumference an inflammation which puts an obstacle in the way of absorption: indurated chancres are the product of a virus of less intensity, which does not develop an inflammation sufficiently strong to hinder absorption. With matter of an intensity different from these, we obtain intermediate forms of chancre, in which, with all our experience, we are uncertain whether or not the primary affection will be succeeded by constitutional syphilis."

Sperino holds that there is only one syphilitic virus, the immediate and mediate effects of which are different,

according to whether it has or has not undergone a modification through the lymphatic ganglions. ('Lancet,' 1864.)

Robert, a distinguished surgeon at Marseilles, and formerly a pupil of Ricord's, says the different varieties of the primitive affection are simply to be considered as manifestations of a single principle, the various effects of which depend upon conditions extraneous to the virus. (Maunder's 'Trans. Ricord.')

Are the several manifestations of syphilis evolved in any definite order; and is the character of chancre any index to such manifestations?

The compiler of Ricord's lectures gives this quotation from Ambrose Paré: "If there is an ulcer on the penis, and if the part is hardened, it will be an infallible sign that the patient is affected with syphilis." (Maunder's 'Trans. Ricord.'

Ricord says: "The first sign of constitutional infection is induration of the chancre, which is invariably followed by constitutional symptoms." By which I understand Ricord to mean that induration of a chancre is a secondary manifestation, never existing alone, but always followed by *other* secondary symptoms. I agree that it is quite possible—nay, even probable—that the chancre, as the weakest point of the economy, may first suffer. I, at the same time, see no reason why the syphilitic poison may not be exhausted here, as the poisons of other diseases sometimes are in a single pustule.

The following opinion of Ricord's has been subscribed to by most syphilographers:—"Of the two varieties of chancre, the form most commonly met with is the non-infecting. It is, then, correct to state that, in the great majority of cases, the chancre does not induce syphilis." Were this literally true, it might, indeed, account for the fact that comparatively few chancres are followed by constitutional symptoms. I believe, however, that this dogma is founded upon error; and in support of this belief let us analyse the statistics collected by Fournier for Ricord at different periods amongst the patients of the Midi, and which I extract from Maunder's 'Translation of Ricord':—

During three months, number of *chancres* seen	341
Chancres indurated	126
Ditto simple	215

Now Ricord states: "The simple chancre is generally multiple; the indurated chancre, solitary." Consequently more than *one-half the patients*, according to his dogma, should have had constitutional symptoms.

At page 28 it is stated that *patients* affected with simple chancres during the year were 254. Now, as we cannot suppose that this number represented one tithe of the patients admitted during that period, all the rest should have had secondary symptoms.

In page 182 it is stated that, of 814 *patients*, 471 had hard chancre; 343 soft. Here again, then, many more than half the patients should have had secondary symptoms.

From these statistics, then, it appears that a greater number of patients suffer from the hard than from the soft chancre. We do not, however, find in practice that half our patients become affected with constitutional symptoms, and consequently we are driven to the conclusion, admitting induration of a chancre to be a secondary manifestation, that the syphilitic virus may exhaust itself at the point of inoculation alone.

Induration of the chancre is, however, by no means the first sign of constitutional infection. This may be delayed, or even never occur, as Mr. Marston's cases show. ('Lancet,' 1862.)

Cullerier says: "The whole diagnosis of chancre does not consist in the local state; and when induration is absent, it must be sought for elsewhere. When induration is absent in a doubtful chancre, it is in the corresponding glands that I seek for the diagnostic element; I will not say complimentary, but indispensable: and I do not see why the infecting reaction, not making itself apparent in the ulceration itself, should not convey its action on the glands, which in this case substitute themselves for the chancre." (Note, Ricord's Lectures.)

Ricord also believes that there can be no infecting chancre without an indurated multiple symptomatic bubo; which bubo, he states, possesses no tendency to inflammation or to undergo specific inflammation. In opposition to this, Mr. Marston states: "Sores occupying the sheath of the penis (almost invariably infecting as I have seen them) do not always give rise to indurated inguinal glands, but an indurated or even suppurating bubo at the root of the penis, and yet be infecting sores; and suppurating buboes are often followed by secondaries, as seen in the army." ('Lancet,' 1862.)

Mr. Langston Parker says: "Ricord has laid down a positive law that a bubo which suppurates specifically—that is to say, which furnishes an inoculable pus—is never followed by secondary symptoms. All I can say is, that buboes which suppurate freely, and to all appearances specifically, are followed in some cases by secondary symptoms."

In 'Lancet,' 1860, Mr. Girdwood, of the Grenadier Guards, has reported several cases of chancre followed by constitutional infection, without the intervention of bubo; and of 100 cases treated by Mr. Green, of Bristol, bubo supervened in 16 only.

The fact is that the presence or character of bubo depends in great measure upon constitutional peculiarities. Every practitioner must have seen patients in whom bubo had been produced by the slightest abrasion or mildest gonorrhœa, whilst no amount of irritation would produce them in others. Both, however, might equally be susceptible of secondary infection.

That the character of the chancre is some index to the secondary manifestations likely to follow, seems probable from the following opinions:—

Mr. Acton states: "I have never myself yet met with any single instance in which, after uncomplicated indurated sore, the secondary disease has extended deeper than the skin or mucous membrane. The bones and deeper structures remain perfectly free from disease. There is no loss of nose, no affection of the bones, of the palate, or those other catastrophes which used to show how powerless the old remedies were. The few cases that we now see in private practice of the worst forms of secondary and tertiary symptoms follow only those phagedænic indurated primary sores that we have described."

To be continued.)

HOSPITAL REPORTS.

By Dr. G. de Gorrequer Griffith.

ROYAL GENERAL DISPENSARY, ST. BARTHOLOMEW'S CLOSE.

On Wednesday, the 10th of August, a man presented himself at the above Dispensary and sought relief from a most severe attack of Urticaria. The entire body, with the exception of the face, was thickly covered with the rash peculiar to this affection; the forearms and the lower extremities, especially the inside of the thighs, had the eruption particularly well marked. The appearance presented by the patient was as though he had been beaten with nettles, and as though the formic acid contained in them, acting as a violent irritant upon the integument, had created inflammation of it, besides causing it to be elevated into distinct white wheals, while it had occasioned that portion of integument, not so elevated, to be engaged in a diffused redness, or an erythematous-like blush. The wheals were of an ovoid rather than a circular shape, and were of a whiter hue than the healthy skin; but were altogether free from vesiculæ.

Concomitant with the above symptoms were intense itchiness and a most disagreeable sense of tingling, irritability of the stomach, and a feeling of general discomfort, proceeding not alone from the gastric disturbance, but also from the sympathy of the head. Giddiness, anxiety, and groundless alarm, lassitude and faintness, were likewise among the symptoms. The rash had been ushered in by febrile symptoms which had, however, subsided on

the appearance of the former, and continued to abate till the eruption had fully declared itself, when little, if any, feverishness remained. So great was the irritation of the integument that the patient could not refrain from scratching and rubbing, and, so, had very much aggravated the blush of redness, increased the eruption where it had already made its appearance, and brought it out in places where it had not yet declared itself.

The hands were enormously swollen, and the fingers, though separated to their fullest extent, were yet in contact with each other, so great was the size which they had attained.

The patient was thirty-five or forty years of age; was of a thin, spare habit; of not very robust health, but yet of very fair condition: he was also temperate in his mode of living, not being over-indulgent in either eating or drinking.

The cause of the affection was supposed to be the ingestion of some skate, of which the man had eaten somewhat heartily previous to the appearance of the rash.

Dr. Sisson, under whose care the patient had placed himself, considered it possible for this nettle-rash to have been produced by the preparation of squill which the man had been taking for the relief of an attack of bronchitis, and mentioned, in the course of some remarks that he made upon the complaint, that although, in this country, it was generally the result of eating shell-fish, there were several species of edible fish in tropical seas which, when eaten, produced effects exactly similar, and that he had seen half a ship's crew affected with this rash after they had partaken of the bonite of the Indian seas.

The treatment adopted was that by emetics and purgatives, and their administration was attended with a happy issue.

By Willan this ailment has been divided into six classes; they are as follows:—Urticaria febrilis; U. conferta; U. evanida; U. tuberosa; U. persistans; U. subcutanea: but for all practical purposes the division into acute and chronic is quite sufficient.

The case which we have reported is a good illustration of the acute form of the malady; although, in some instances, the malady wears a yet more severe character than that we have portrayed.

The rash is usually to be found most thickly spread upon the inner surfaces of the limbs—both upper and lower—and also upon the thighs, the loins, and the shoulders. In the present case the face was free from the rash, but in other instances it will be thickly covered; and the redness will extend to the red margin of the lips, or even, beyond this line, into the interior of the mouth. When the patient gets heated in bed the colour of the eruption becomes a deeper hue. The rash will often fade during certain hours of the day, and towards evening return either to its original tint or to a deeper: this will be specially observable if the patient be exposed to sudden alternations of temperature, or to any great degree of warmth: cold, on the other hand, will be found to exercise repressive action, and to cause the rash to fade. Very often, indeed, from causes which we cannot explain, the eruption disappears in one situation and breaks out in another; or grows fainter in one place while it brightens in another; or, again, it may run its entire course in a few hours, leaving few or, perhaps, no traces of its occurrence. In the majority of instances it lasts a week, or even more, but during all the time of its continuance it is subject to exacerbations.

That form of the affection in which the entire surface of the body is covered with the eruption is called urticaria conferta; and when there is little or no fever, a want of persistency on the part of the eruption, with an irregularity in appearing or disappearing, the term evanida is applied. The urticaria tuberosa is a very severe form; in it the wheals rise up rapidly, and rapidly increase to a very large size: they may be either white, and then in marked contrast with the surrounding red integument, or else of the same colour as the level integument, from which they are to be distinguished by their elevation and by their peculiar hardness. These wheals may be arranged in parallel stripes, or may be placed crosswise as regards each other, or be scattered irregularly over the entire surface; sometimes these tumours attain a size equal to that of the palm of the hand, and are excessively tender and painful: they do not usually continue in this state for more than a few hours, and when they disappear they leave a painful sense of discomfort, and a certain degree of weariness and lassitude. When, instead of disappearing, the wheals continue, and that, too, after the erythematous blush has faded or entirely passed away from the skin, the name, urticaria persistans, is applied to the affection. In some instances we have known these welts or tumours to continue for three or four weeks.

The urticaria subcutanea of Willan is that form in which there is no redness, but only an eruption of wheals, which lasts perhaps a few hours, and then disappears, to be again, after a short time, succeeded by another eruption of the same nature. The wheals may remain for some days and then disappear, but without affording the patient any relief from his general discomfort.

In those instances where the affection arises from the ingestion of an irritant, it is not usual to have any febrile disturbance premonitory to the eruption; there may be, however, instead, pain in the region of the stomach, nausea, vomiting, vertigo, a sensation of sinking, and a most distressing feeling of anxiety. When the eruption appears, the body may be swollen to a very large size, owing to the irritated or inflamed state of the integument; and this swelling will, in a number of instances, be attended with difficulty of breathing. All these symptoms will very frequently be relieved, or entirely removed, either by the vomiting incidental to the affection or that occasioned by the administration of emetics; that is, if the malady has been produced by something taken into the stomach.

It is well known that all kinds of shellfish, when taken into the stomach, are the most frequent cause of this nettle-rash; but the ingestion of, perhaps, no other kind of shellfish causes it so frequently as does that of mussels. Shellfish alone cannot be charged with the origination of the urticaria, inasmuch as all other kind of fish will have in some people the same effects; moreover, particular parts of fish, or fish eaten in certain states of health of the person eating, or at a time when the fish is not in season, will cause the appearance of the urticarious condition. The part of the fish which is most likely to occasion this rash is the fat, in which it is supposed that the noxious irritating property resides.

Other edible articles than fish will produce these distressing symptoms which we have been describing, nor is the eating of flesh food alone attended with them: vegetables, especially those eaten in their raw or uncooked state; fruits, no matter how ripe or how easily digestible by the stomach of ordinary persons; that is, persons free from the idiosyncrasy which predisposes to this ailment; medicines, such as the turpentines and the balsams—are all of them known to give origin to the eruption.

Nor is its production confined to these agencies. There are certain conditions of the system—physical, mental, or otherwise—which not only predispose to it, but are likewise direct or exciting powers. Among these we may enumerate excessive exercise, more particularly if great perspiration be induced; intense anxiety; great excitement of spirits, or sometimes great depression; the imbibition of ardent spirits, or of any substance which, when passing off in the perspiration, creates irritation of the sudoriferous ducts and of the integument; the ingestion of indigestible, or of very highly seasoned, or of very rich food. The exposure of the surface of the body to heat after cold, or, as takes place in some instances, the mere reaction which sets in after cold has been applied for some time, are often of themselves sufficient to induce the appearance of the rash.

It may be an epidemic. Persons with thin and delicate skin are especially liable to become the subjects of the complaint; and more particularly so if there should be in their constitution any tendency to the gouty or rheumatic diathesis. In such instances as these the eruption will show itself, and very speedily, after very trivial causes;

and though it will yield readily to treatment, and be made rapidly to disappear, yet will it again quickly return.

We have laid it down as a truism that those persons having thin, delicate skin are most liable to be affected; inasmuch, therefore, as females and children come under the head of such a class, we naturally look for its prevalence amongst them: nor are we disappointed in our expectations. The younger the person, and the more delicately constituted, the greater is the predisposition; and should the temperament be the sanguine, this predisposition is heightened.

We shall now direct attention to the diagnosis of the eruption, since such is necessary, inasmuch as the disease may be present at the same time with lichen, impetigo, roseola, or with the common erythema, or the erythema nodosum. From this last it is distinguished by the want of durability of continuance on the part of the tumours incidental to the erythema; in the erythema, likewise, there is not that tingling and itching which form so distressing a feature in the urticaria. Lichen urticatus very closely resembles the affection of which we are treating; so closely, indeed, that some care is needed in making our diagnosis before we can pronounce a determinate opinion. The lichen has, however, the wheals of a smaller size, more firm in their consistence, not so much elevated above the surrounding surface, but of a deeper tint and more lasting; another difference, which is pathognomonic, is that the wheals of the lichen are studded with distinct papulæ.

In general, the peculiar sensations of true urticaria, the harassing itching and tingling, the size and condition of the wheals, the redness of that portion of integument which is not raised, the swelling and puffiness of the entire skin, are all of them very demonstrative of the exact nature of the affection, which we may be called upon to treat; and if carefully put together, collated, and considered, will assuredly enable us to arrive at a true conclusion.

We shall now advert to the treatment necessary for the alleviation or cure of this malady.

In this case of Dr. Sisson's, we have seen that recovery was obtained by the administration of emetics and purgatives; indeed, in the majority of cases, little else is necessary; and in a large number of instances medical treatment is not at all required; abstinence from those articles, or the removal of those causes—predisposing or exciting—which occasion the affection being alone sufficient.

Emetics should be administered at an early stage of the complaint if ingested substances be at fault; but they should be of such mild nature as not to cause any depressant action, or, at least, as little as possible. It is always advisable to clear out the bowels with aperient medicine, whether we choose to give it by the mouth or by the anus; in making a selection of the method of introducing the medicine, we are often guided, not by any wish on our own part, but by the contingencies of the case.

In those patients who are of a rheumatic or gouty diathesis, the remedies suitable to such temperaments must be used; when there is very great cutaneous irritation, it may be allayed or removed by means of some sedative medicines; and when nervous depression exists, the indication for the use of camphor, ether, or other nervous stimulants is present.

The best emetic we can select is the ipecacuanha, because, in its effects, it is both certain and efficacious, and unattended with the distress attendant upon severer emetics.

In the form of the ailment known as urticaria subcutanea, tepid and warm baths will be found to afford, in many cases, considerable relief; in other instances of the affection, where there is a plethoric habit of body, more severe measures are required, perhaps even so severe as the taking away of blood. But we need scarcely say that this is a mode of treatment not to be lightly undertaken.

Inasmuch as there is always, or at least very frequently, acidity of the secretions of the stomach and bowels, it is always best to select medicines—purgatives, for instance—or alteratives, possessing antacid properties; in cases where there is decided acridity, and where it prevails to a marked degree, we shall find it beneficial to treat the sufferer with magnesia or the liquor potassæ: but though this holds good as a general rule, yet there are instances in which the very opposite method of treatment—namely, by the use of acids—will be found to be effectual in restoring the patient to health. When there is a tendency to intermissions in the eruption and in the other symptoms of the affection, the sulphate of quinine is said to be not valueless; arsenic has been administered, and with good effect; and by some a gentle course of mercury has been recommended, with the object of removing from the blood any deteriorating or offending agent, and at the same time restoring it to its natural healthy standard.

We have already adverted to local treatment when we advised the use of warm baths, but here we would point more particularly to that treatment. If we use the warm bath, the temperature of it should be sufficient to promote good diaphoretic action of the skin; and in order to correct the excessive acidity of the sudorific excretion, it will be of use to render the water of the bath alkaline by means of the carbonate of potass or soda. The vapour bath also acts efficaciously. We must be very cautious in applying cold to the surface, lest we occasion a retrocession of the rash and a fatal metastasis; and when there is any symptom indicative of a tendency to retrocession, we should at once begin the use of the warm or of the vapour bath, so as effectually to recall the eruption.

PARISIAN MEDICAL NEWS.

HOSPITAL OF THE SCHOOL OF MEDICINE. PROFESSOR NELATON'S WARDS.

Sub-ungual Exostosis.

Twelve months ago, a young working man, aged eighteen, observed that the nail of the great toe of his right foot was gradually assuming an improper direction. The extremity of the nail was growing upwards like the point of a mediæval shoe, and occasioned inconvenience and even pain in walking. The incision of the exuberant portion of the nail gave but little relief, the outer edge of the toe was swelled and tender, and the patient applied to M. Nélaton for the cure of an affection which often obliged him to discontinue his habitual occupations. The Professor easily detected in the painful part a small round tumour protruding beyond the point of the toe, and extending beneath the nail which it raised; the tumour was red, covered with minute pellicles, and presented an orifice from which pressure forced a droplet of puriform matter. The firm consistency of the swelling pointed to the diagnosis; an osseous growth alone could possibly cause the symptoms observed; and as the Professor surmised, the case proved to be an instance of the disease described by Dupuytren under the denomination of exostosis of the upper surface of the great toe, or sub-ungual exostosis.

The great toe alone is almost invariably the seat of the affection, which is very seldom indeed observed on any of the other toes; once only M. Nélaton met with it in one of the fingers of the hand. It must further be remarked that in nine cases out of ten the exostosis occupies the wider part of the dorsal aspect of the bone, near its external edge, and at the juncture of the lower with the middle third of the phalanx. The aspect of the tumour is characteristic; its shape is conical, and the nucleus is an areolar texture exactly similar to that of the bone, the osseous substance lying in strata, beneath a layer of cartilage, covered by an epidermic, horny cuticle.

In such a case, the incurvation of the nail upwards, and the consequent distress in walking, first attract the patient's attention. Paring of the nail is, of course, resorted to, and this measure is sometimes sufficient to remove the pain; and as in many instances a protecting horny excrescence, of moderate thickness, forms on the surface, the inconvenience is bearable. But it occasionally happens, as in the case which suggests the present remarks, that the external covering of the growth inflames from the friction of the shoe, and walking becomes difficult or impossible.

The treatment is then plainly indicated, and the exostosis must be removed. M. Nélaton proceeds as follows to the performance of this rather painful operation :—A muslin bag filled with salt and pounded ice is applied for two or three minutes over the toe, in order to deaden sensation, and with a short and strong bladed knife, the tumour is isolated and removed ; sometimes the gouge and mallet must be used. The dressing should be of the simplest character, and in the course of twelve days or a fortnight, healthy granulations form and a solid cicatrix follows. This procedure was instituted by M. Nélaton in the case above adverted to, and the result was in every respect satisfactory.—'Journal of Practical Medicine and Surgery.

SYPHILITIC TUMOUR OF THE GLUTEAL REGION.

Although syphilitic tumours of the soft parts are now better known than formerly, they often, especially in women, give rise to errors of diagnosis. We may, in illustration of this remark, allude to the case of a woman recently admitted into M. Nélaton's wards for a swelling in the gluteal region, which, before the patient's entrance into the hospital, had occasioned much difference of opinion. The tumour was flat, as broad as the hand, and formed a hard and movable mass, separated from the rectum by a band of healthy tissue. The skin had assumed the roseate purple hue characteristic of chronic inflammation; it had partially lost its elasticity, and some amount of œdema was present—a circumstance demonstrated by slight pitting after pressure with the finger. In addition, although it was not impossible to discover the limits of the tumour, its margin was vague and ill defined, a pathognomonic character of syphilitic nodes. The patient was perfectly sincere in her earnest declaration that she had never been affected with syphilis ; but, despite her denial, M. Nélaton's first impression remained unaltered. By close and searching interrogation as to her former health, he elicited the fact that eighteen years before she had suffered from obstinate sore-throat; that since then she had been liable to what she called cramps, which had obviously been genuine osteocopes, a surmise borne out by the undulating thickness of the ridge of the tibia. These indications amply justified the suspicions entertained as to the nature of the case, and pointed to the most appropriate treatment.

Antisyphilitic remedies supply, moreover, a delicate test of the accuracy of the diagnosis ; and as they are harmless, if prescribed with discretion, it is perfectly legitimate to resort to them even on the strength of mere presumptive evidence.

The most efficient remedy in tertiary disease is iodide of potassium (gr. xv. daily). If the tumour be a syphilitic manifestation, improvement promptly sets in under the influence of this medicine, and in a few days the mass disperses ; in the present instance the effects of the drug were extremely remarkable. In some cases it is necessary to exhibit mercury at the same time with the iodide of potassium. But occasionally, in spite of all treatment, an abscess forms, and the subcutaneous cellular tissue mortifies and falls away like the core of an anthrax, leaving an ulcer which follows the same progress as other sores of syphilitic origin. *Ibid.*

REDUCTION OF VOLUMINOUS HERNIA BY ELASTIC PRESSURE.

A man was admitted into hospital for alleged hydrocele. The scrotum was the seat of a chronic enlargement of such considerable magnitude that a superficial depression alone indicated the situation of the meatus. Sexual intercourse was utterly impracticable, and the patient complained of great inconvenience in walking ; in addition, the contact of the urine with the skin gave rise to painful excoriation, colic was present, and the infirmity was altogether of a most distressing character.

The patient had been informed that he was affected with hydrocele ; but this was a mistake. Both testicles were easily felt perfectly distinct from the mass—a circumstance incompatible with the existence of dropsy of the tunica vaginalis ; on percussion a degree of resonance was, moreover, perceptible, which could not be produced by hydrocele of the cord. This tympanitic sound demonstrated the true nature of the disease, which consisted in enormous inguinal hernia, with a voluminous pedicle, presenting all the characteristics of entero-epiplocele.

This kind of ancient and voluminous hernia distends the scrotum, is not liable to incarceration, and gave rise in the last century to active controversy, which led to such tumours being pronounced to be irreducible. Surgeons dreaded the restoration into the abdomen of organs which had long been displaced, and had lost what Jean Louis Petit called their "*droit de domicile*" within that cavity. M. Nélaton acknowledges that he once entertained a similar view, but on further reflection he has since altered his opinion, and now professes that the reduction of these herniæ may legitimately be attempted, and that it is possible to effect this desirable result without injury to the patient. This, however, cannot be accomplished at once ; and the perils adverted to by Jean Louis Petit doubtless arose from the fact that the tumours he alludes to were reduced in an incautiously precipitate manner. Ravaton adopted a safer practice, and endeavoured slowly to attain the same object by compelling the patients to lie for a long time on their back. Several of the individuals under his care thus remained for six weeks in bed, with much ultimate benefit. M. Nélaton remarked that, in a case of fracture of the femur in a man who for months had borne a large unreduced hernia, M. Sanson had taken advantage of the compulsory attitude enforced on his patient, and gradually returned the intestine into the abdomen ; no untoward accidents followed, and M. Nélaton has since very frequently resorted, with advantage, to the same method. The time necessary to attain the desired result may be shortened, if to the indispensable position be added pressure with M. Maisonneuve's elastic bands. These measures were adopted in the case here alluded to, and the hernia is now entirely reduced. A well-made truss has been applied, and no functional disturbance has supervened to justify the apprehensions formerly suggested by the method resorted to in this instance, which, it is true, would not, in Jean Louis Petit's time, have been instituted in the same manner. *Ibid.*

THE BRITISH MEDICAL ASSOCIATION.

JOHN BRIDGER, Esq., of Cottenham, made the following observations

ON DIPHTHERIA.

Since April, 1862, upwards of 3,000 cases of diphtheria have fallen under my care. At the onset of the epidemic the disease was of a more acute character than at the present time, cases then presenting the characteristic appearances so well-known to the Profession, and so ably described in a lecture by Dr. W. H. Ranking, delivered at the Norwich Hospital—*vide* 'Lancet,' January 8, 1859.

Latterly most of the cases have been of a milder character, very many of them relapses. The sequelæ are often very serious, such as pleurisy, pleuropneumonia, endocarditis, peritonitis, croup, paralysis, &c., &c. ; in one case there was abscess of the liver, in one gangrene of the lung ; some have passed membrane from the bowel, one from the bladder. Erysipelas has very frequently followed, sometimes commencing at the nostrils, and spreading over the face and head, sometimes from one or both ears, and spreading over the head and face, in a few cases from the anus, umbilicus, penis, or vagina, and extending slowly over the whole body and lower extremities ; in the three last-mentioned points of commencement it has occurred in infants that took the disease from their mothers, and showed it either at birth or within a few days. Women who have the disease previous to or during pregnancy have their condition modified by it ; in some it produces abortion, in some premature confinement, in others hæmorrhage or lingering labour; whilst in all puerperal women, for a period of from three to six weeks after delivery, and

occurring every few days, there is a discharge of shreddy membranous or glairy matter, like uncoagulated white of egg; this has occurred in fifty-two cases, my attention being generally called to it by the patient or nurse as something unusual.

The children born of these affected parents invariably show signs of the disease soon after birth; if you look into their throats you see the tonsils, uvula, and soft palate swollen and red, perhaps slightly œdematous, producing a slight hoarseness and cough; this may go on for some days, or even weeks, the child, seeming neither well nor ill, all at once is taken worse, screams out with pain, and dies in a few minutes. Whenever I have been able to examine the body I find death caused by effusion into the pericardium. Altogether, out of this number of cases, there have been seventy-five deaths. Twelve were complicated with scarlet fever, nine were complicated with measles, one with confinement and scarlet fever, one with confinement alone. A primipara, a young woman aged twenty-one years, gave birth to an acephalous child, and was doing well up to the twelfth day, when she complained of her throat, the tonsils, soft palate, and uvula looking red only. In about twenty-four hours she complained of a kicking sensation in the throat, screamed out, and died. No post-mortem was allowed.

I have made twenty-four post-mortem examinations, and wish particularly to bring before the notice of the members of this Association a certain condition of the auriculo-ventricular valves of the heart seen in every case where a post-mortem was allowed, whether complicated with any other disease or not, and to the best of my belief not previously made known to the Profession. It is a roughened, reddened, and thickened appearance of the valve, as if by interstitial deposit, situated midway between its insertion around the ventricular opening and the attachment of the chordeæ tendineæ, one or both valves being affected more or less, according to the severity of the case and the time elapsing between the symptoms of heart affection and death. The symptoms denoting it may come on early or late, generally late, several cases having occurred where to all appearances the patient has been well, and may be diagnosed by the following symptoms:—An anxious countenance, hurried respiration, a rapid pulse (from 120 to 170), tenderness over the precordial region, scarcely any pain excepting on pressure. In four cases I noticed a slight murmur, systolic; in two it subsided in a week; one remained permanent for some months; one case is now under treatment, and at this present time there is a distinct bruit heard at the base over the valves, and along the course of the aorta. The duration of the urgent symptoms varies from three to seven days, the shortest being three, the longest seven days.

I have not noted the exact number of cases in which the heart has been so affected, but can safely say it occurred in at least a hundred; in some it came on most severely, and was like a state of collapse, with cold clammy perspirations.

In this endocardial affection I give the steel mixture with nitrate of potass every two, three, or four hours, a small dose of grey powder, with compound ipecacuhana every night, and apply a sinapism twice daily until the pain and tenderness on pressure subside. In the cases with a bruit, and also accompanied by pain, gr. iij. of the extract of conium is given every four or six hours as long as required.

In all cases where membrane extended down into the trachea and lesser bronchi death followed rapidly. In those cases simulating spasmodic croup, with patches of membrane on the tonsils only, five have died, three recovered. One patient, a lad, aged fourteen years, died suddenly in getting from the bed to the night-stool, apparently from paralysis of the heart, as he was previously doing well and getting about the house; his mother had given him a dose of castor-oil contrary to my wishes.

In respect to the treatment generally pursued, I rely principally on the tincture of sesquichloride of iron, but combine with it the acetate of ammonia and spirits of nitrous ether in order to keep the skin and kidneys active. When there are glandular enlargements, I add to these the iodide of potassium; and should there be also an œdematous condition together with glandular enlargements, both the iodide of potassium and the chlorate of potass. If the tongue be much loaded, and the patient feel at all sick, I generally give a stimulating emetic of equal parts of sulphate of zinc and ipecacuhana; throughout the active stage of the disease an alterative dose of calomel or grey powder combined with the compound ipecacuhana is given every night at bed time. I apply emollients or stimulating fomentations to the throat externally, and direct the patient to gargle with warm water or weak vinegar-and-water frequently, unless there be very much fœtor. I then substitute a weak solution of chlorinated soda. The forcible removal of membrane and the application of acids or caustics I think quite useless; in fact, I believe they are injurious, producing shock and afterwards greater depression. Perfect rest and quiet are necessary; beef tea and stimulants, either brandy or wine, as best suited to the case. When indications of approaching paralysis show themselves, I add to the steel mixture small doses of strychnine, thus, I believe, in very many cases obtaining a more rapid convalescence than can be obtained by any other tonic, such as quinine, bark, and the mineral acids, all of which I have tried. Acids I find are not generally tolerated. In some special cases where you have a large amount of semi-fluid fœtid discharge from the mouth and nostrils, the solution of chlorine (made by adding a dilute hydrochloric acid to chlorate of potass) combined with the steel, and given every two or three hours, I have found to act almost magically in checking this discharge and producing rapid convalescence. In fact, I find generally that the chlorate of potass with steel to young children is not only the pleasantest, but the best remedy, bringing back the colour to the lips and cheeks sooner than anything else. In cases of croup I give calomel gr.j., ipecac. gr.ij., as a mild emetic every two, three, or four hours, and during the intervals the steel mixture with nitrate of potass and small doses of chloroform, applying externally to the throat and chest fomentations of hot mustard-and-water, discontinuing the calomel and ipecac. as soon as the urgent symptoms pass off, but continuing the steel mixture. Dr. Paget saw several cases, and amongst them one of these croupal cases. After death I sent the larynx and heart for his inspection.

Change of air I have found absolutely necessary in some cases; it is beneficial in all. Being situated on the border of the Fens, our atmosphere is of a very depressing character, and those persons who come from a higher elevation and more bracing atmosphere to reside in this neighbourhood generally take the disease.

On several occasions when there has been a batch of fresh cases those already ill have been taken worse on a particular day and hour and in a particular direction, as if the disease were caused by a wave passing over in this direction from village to village.

I do not pretend to know or assign the causes or origin of this disease, but I believe with many others that it is a disease affecting the whole system through the medium of the circulation, and always producing affections of an asthenic character; and that when it attacks persons of a tubercular diathesis, if not immediately fatal, it lights up the tubercular disease and hurries rapidly on to a fatal termination cases that probably might otherwise have lived for years.

C. B. RADCLIFFE, M.D.Lond., spoke

A FEW WORDS CONCERNING BANTINGISM.

As every one knows, Mr. Banting was a stout man who became reduced to more seemly dimensions by the adoption of a particular code of diet. As every one also knows, "Bantingism," or the struggle to become thin by following Mr. Banting's example, is, at present, the fashion in many quarters. Is, then, this fashion to be encouraged, or is it to be discouraged? Dr. Radcliffe is of opinion that it ought to be discouraged, and the present "few words" are intended to show in brief what it ought to be.

Mr. Banting's rule is to take abundance of lean meat, claret,

sherry, Madeira, and tea, and to abstain, as much as possible, from bread, butter, milk, tea, sugar, beer, and potatoes —articles containing starch and saccharine matter—to abstain as much as possible from the articles upon which Mr Banting had lived almost exclusively in the days when he was a victim to obesity. The diet in Bantingism, indeed, is essentially the same as that prescribed in training for the ring or for the boat race. The chief peculiarity in each case is to allow a large amount of lean meat, and if there be any differance it is that the Bantingist deals more liberally with himself in this respect than the athlete. What Mr. Banting allows himself is rather more than is eaten by the average-sized man in training. It may be expected, therefore, that the known results of the process of training may throw some light upon some of the consequences of Bantingism. It may be expected that Bantingism cannot be carried beyond a certain point with advantage. In training this is certainly the case, for after a certain time, longer or shorter as the case may be, after within four months at the longest, the person in training rapidly gets "out of condition." Nor is it otherwise with Bantingism; at any rate, Dr. Radcliffe says that he has met with several persons who, after trying Bantingism for a while with no disadvantage, having thus got "out of condition" in an unmistakable manner, some of them becoming very gouty, and all of them experiencing a decided failure in strength and spirits.

Dr. Radcliffe is disposed to look upon this loss of "condition" in these two cases of training and Bantingism as depending partly upon excess of nitrogenised food and partly upon deficiency of fatty matter. The nitrogen of the food escapes in the main by the kidney as urea or uric acid, and if the kidney be not up to its work the system is apt to become gouty from the accumulation of these products in the blood. Hence it is not difficult to see how excess of nitrogenised food may, sooner or later, lead to ill-health, and that especially in the case in which a proper amount of exercise is neglected. Nor is it difficult to see how deficiency of fatty matter may tend to bring about the same result, if, as Dr. Radcliffe supposes, a certain quantity of fatty matter be necessary to the proper nourishment of nerve-tissue. It is not difficult to see that nerve-tissue, which contains a large quantity of fat, may be starved if the food do not contain a sufficient quantity of fat, and that this starving of the tissue may involve a corresponding want of nervous energy. At any rate, Dr. Radcliffe is disposed to look upon the diet in training and in Bantingism as calculated to nourish the muscles rather than the nerves, and he believes that this may be one reason why prize-fighters, like Heenan, have often been so seriously wanting in the power of sustained action, and why the followers of Mr. Banting have, after a while, begun to flag in the spirit which animated them at first.

In a word, Dr. Radcliffe considers that it is not safe to ignore the whole standards of food so completely as is done in Bantingism. He thinks that milk and bread are still typical articles of food. He gave reasons for believing that the farinaceous, and saccharine, and oily articles of food are, in proper proportion, not to be dispensed with without risk, inasmuch as they are the most suitable fuel for keeping up the heat of the human body at the proper point; and he gave reasons, also, for doubting whether saccharine and farinaceous matters in excess have the same tendency to favour the formation of fat as oily matters in excess. He is of opinion that certain persons may incline to the type of vegetable feeders rather than to the type of animal feeders, and that these persons may find the nitrogenised part of their food better in the albumen, fibrine, and caseine of vegetables than in the albumen, fibrine, and caseine of animals.

Royal Medical College, Epsom.—The Right Hon. Earl Granville, K.G., Chancellor of the University of London, has accepted the office of President of the Medical College at Epsom.

MEDICAL ETIQUETTE. — THE WIMBLEDON ACCIDENT.

The death of poor Cooper from the effects of the accident at Wimbledon during the rifle contest will be seen with regret by most of our readers as casting a shade over that otherwise successful demonstration. The reports had induced a hope that he might recover—a hope which was not shared in by those who had seen from the first the real nature of the injuries received. A good deal of interest has been excited as to the alleged maltreatment of the case. It appears that immediately on the occurrence of the accident Dr. Westmacott, who is Senior Assistant-Surgeon to the London Scottish, and also to the National Rifle Association, was called to attend upon the wounded man. After holding a consultation with other volunteer surgeons, and the Assistant-Surgeon in charge of the Guards, it was agreed that the wound was of a very serious nature, and that to extract the ball would be almost certain death: an opinion which was concurred in by Mr. Prescott Hewitt, who was telegraphed down from London, and expressed himself perfectly satisfied with the course pursued. This treatment was animadverted upon by Surgeon-Major Wyatt, in a letter to the 'Times,' as being inconsistent with military usage, which requires that a ball should be extracted at once, let the consequences be what they may. Now we are not at all inclined to enter into the question of the desirability or non-desirability of this rule. Of course on the field of battle, where there are none of the appliances and comforts of home treatment, action must be prompt almost without regard of consequences. But we can hardly draw a parallel between an accident, such as that at Wimbledon, and a wound received in battle. Surely when it was possible to give the sufferer a chance of recovery, any rule, even the most stringent, may be put on one side, and everything done to add to his comfort, and if possible restoration. We would not, however, dwell upon this question. We rather wish to say a word or two about the rights of the Volunteer, as despised, it would seem, by the regular Army Surgeons. Surely if medical officers are appointed to the corps they must have full powers without being subject to be overhauled in the public prints by those who, whilst holding a higher rank, are yet, from the fact of absence from the spot, necessarily unacquainted with the circumstances of the case. Consultations are always desirable, and no one would for a moment object to hear the opinions of others who have had experience in similar cases. Dr. Westmacott, indeed, in his letter to the 'Lancet,' expresses his gratitude for the assistance furnished by those who tendered their advice to him in the first instance, but this is very different to being informed for the first time through the columns of the 'Times' that another, just arrived on the spot, disapproved of the treatment he had pursued, being perhaps ignorant of the fact that Dr. Westmacott was not altogether unacquainted with gunshot wounds, having had considerable experience abroad, and was only deterred from operating at once by the result of the consultation. Meanwhile, we trust that the medical officers of both services will work together in real and perfect harmony. They are on an equality as regards their professional rank. In many cases the volunteers have had as much or more experience. Surely, if they are declared to be fit for the treatment of disease and to exercise the art of surgery in one instance they are in another, and the death of poor Cooper is no ground for supposing the volunteers unequal to the care of gunshot wounds. The 'Lancet,' in an article quoted by the 'Times,' describes the conduct of Mr. Wyatt as "unprofessional, and totally uncalled for;" adding that, "whilst entitled to have an opinion of his own, he is only degrading himself in the estimation of his professional brethren when he obtrudes that opinion upon the public in an offensive letter." Language like this will show what the feeling of the Profession is in the matter. It remains for the intelligent public to uphold the rights of the volunteers against the insinuations of such men as Surgeon-Major Wyatt, believing that the medical, as well as the other officers and privates, are—in fact as well as in name—thoroughly effective.—'John Bull.'

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 24, 1864.

THE UNIVERSITY OF CAMBRIDGE AND THE PROFESSION OF MEDICINE.

Few indeed are the inducements that Medicine has to offer to the youth of our land, who, seeking to travel along the pathway to fame, at the same time seek the means to pay the various toll-bars on the road; for Medicine, like an elder daughter who is not a favourite, receives but a small share of Fortune's partial love, while her younger sisters are pet children.

Many, almost innumerable, are the helping hands extended to the sons of the Church and the Bar, who may run quickly forward and, by success, may do honour to their helpers; but from Medicine the helping hands are withdrawn, and, when her sons appear, they are barely permitted to gather up the crumbs that are left perchance on the path. It is true that Medicine has an Astley Cooper prize; Tancred studentships and gold medals also may be added; but these rewards are few, and the aspirants are numerous. What votary of science has not at some time in his career felt his arm paralysed, or even his brain fettered, because his pocket needed replenishment? How many names that would have graced the annals of Medicine, as many bright luminaries have graced the annals of the Church and the Bar, have been lost, because they had neither means nor friends to tear away the curtain of their obscurity and bring their works to light; and how many are there now whose names might adorn their Profession if only the barriers were removed, and the golden bridge afforded to other professions were but supplied to Medicine to carry its votaries over that precipitous gulf—Necessity.

But while we have fresh in our minds the cordial welcome given to the British Medical Association lately assembled at Cambridge, we cannot omit to notice that this great mother of learning has but few crumbs for her scientific children. While our Profession was feasting at a sumptuous board at Caius College, we were told we were dining in the nursery of many of our most eminent brethren; but while we give due honour to the memory of Dr. Caius and the other benefactors of the College he founded, we must not forget that we were also entertained by a College founded solely by Sir George Downing, who devised by his will, dated 1717, that a college should be founded, the objects, as stated in the charter, being the cultivation of law and physic. Nor was this all; for he left a provision for the Master and two Professors, one in each of the above studies, as well as for at least eight fellows and at least ten scholars on the foundation, besides minor scholarships. Two only of the fellowships are of open choice of profession, the holders being required to act as tutors of the College, and one of these is required to be in orders; while all the others are intended for starting in life as members of the professions of Medicine and Law. The scholarships are not definitely stated to be given to students of Physic and the Bar exclusively, but the intention evidently is that they should have priority.

We are sorry to find that a feeling still exists among those in power that mathematical and classical knowledge should have almost exclusive claim to emolument, and that they think the scholars have no right to expect fellowships unless they have first taken high honours in either of those branches of education. We do not argue for an instant that the physician should be one whit less educated than the clergyman, but we would urge, that whereas the rigid discipline of mathematics and classics well fits the mind for the professions of the Church or the Bar, so also the studies of inductive or natural science equally fit a man for the profession of Medicine and refine the feelings in a more exquisite degree. The standard of Tripos examination is equal, or may be made equal, in both cases, and it is cruel that the rewards are not equal also. The idea which seems to impress the minds of those who hold the reins is this, that the doctor is not equal to a barrister or a minister unless he has taken the same degree in mathematical or classical honours; but if he possesses this equality they will bestow a fellowship on the condition that Medicine be pursued, forgetful that the best time has been expended in obtaining the first honour. It is unreasonable to believe that, as a rule, a man whose brain is worn over his labours to enable him to shine in his first honours can excel in a second against one who commences the study with him, but with a youthful and unfettered mind; thus, practically, the ablest men do not reap the emolument, and their due must fall to the lot of those below them. Again, why should two or three years be added to a university course, which is necessary if a B.A. in mathematical or classical honours must be obtained before Medicine is studied in the university?

It is true the statutes will bear this interpretation put upon them, but we look for a day when Cambridge will exult over her men of natural science and bestow on them equal honour and emolument with her world-famed wranglers. She enforces a previous examination—an excellent and sufficient test of general education,—and we should rejoice to see some of her fosterlings, after they have satisfied her in this test, permitted to study natural science and Medicine exclusively, and the most worthy crowned with the same laurels as those who have achieved success in her older studies.

The advantages of Downing College to the student of Medicine are very great. Any youth in the kingdom is eligible for a minor scholarship; the examination takes place in or about June, and the subjects are natural or moral science, or mathematics or classics. The candidate must at the same time give evidence that he can pass the University previous examination. This year four candidates were elected—two for natural science, one for law and natural science, and one for classics,—the values of each 40*l.* per annum for two years. The minor scholars are eligible in their first year to compete with the other pupils of the College for foundation scholarships. The value of these

is 50*l.* per annum for three years, with the addition usually of rooms rent free, and an allowance of 10s. 6d. a week during term time for commons. Proficiency in any one of the four subjects will secure these advantages on the same conditions of ability to pass the previous examination. We feel bound to lay stress on this latter point, because we know of one instance where a scholarship was refused to a pupil who had satisfied the Scholarship examiners because he had failed to pass the previous examination. Even, however, in this case, the College made a pecuniary recognition of his standing, and we have little doubt will award him a scholarship when the little-go is accomplished.

At present only two foundation scholarships have been given for natural science, and only one for moral science; nevertheless, most of the mathematical and classical ones have been bestowed on intending barristers.

We believe that, in October next, the new chemical laboratory of Downing College will be in full operation for the use of the students, and lectures and special instruction will be given on the various subjects of examination in the Natural Science Tripos, which, through the able tutorship and endeavours of Dr. Latham, will be even more advantageous to the student than private tuition. An important benefit to a student of Medicine at Downing is its close proximity to the Museum, the new Medical School, Addenbrooke's Hospital, and the Botanic Garden; and the pupil of Downing can be at any one of them within a few minutes of leaving his college rooms. Downing has a very fair Medical library, to which additions are constantly made of such books that a student needs or feels in want of as a reference. The rooms of Downing rival in luxury and convenience those of any other college in Cambridge; the College stands in the centre of its own grounds, and the freedom from noise is particularly pleasing to a reading man; while the quiet, gentlemanly bearing of Downing men not only renders their society to be courted in the university, but also renders unnecessary the rigid discipline which is required to be carried out with much strictness in large colleges.

There are some minor grievances at Downing which, no doubt, the authorities will soon rectify; but the advantages of the College outbalance the petty annoyances. Not only are the resident tutors kind friends to all the pupils, but they use every endeavour to help them in their studies; and the marked kindness that the Natural Science men have received in preparing for the previous examination deserves the most flattering and complimentary notice: nor should the kindness of the Downing Professors to pupils of the College pass unacknowledged.

In conclusion, we would remind those who are about to study Medicine in Cambridge, that if they are fortunate enough to hold a Downing scholarship, and succeed in taking first-class honours in any Tripos, they retain all the advantages of a scholar till either they are of standing to take the M.A. degree or are elected to a fellowship.

We cannot at present hold out much hope of a Fellowship in Medicine or Natural Science unless the door of mathematical or classical honours shall give the admission; but we believe the letter of the statutes intends the emolument for Law and Physic only. We not only feel sure that the present governing society will uphold their statutes to the letter, but hope they will ere long set an example to prove to other colleges that England's science is England's refinement and civilization and learning; that England's Doctors are an honour of her country; and that they will recognise the value of the labourers of Physical and Natural Science, by crowning with equal rewards those who achieve success equally with the mathematicians, the more favoured children of the great university, whose training fits them to wear their laurels most fittingly in the honoured professions of the Church and the Bar.

SUMMARY OF THE WEEK.

A LATE CASE OF ALLEGED MALPRAXIS.

Although rather late in the day, considering the rapidity with which current events are forgotten, we cannot refrain from offering a few observations on the case of Smithyman *v.* Wilson, which was tried at the last Shrewsbury Assizes. The plaintiff was a mechanic, who had had a severe fall and injured his shoulder, and for the injury he consulted the defendant, who detected a dislocation, and, with the assistance of a person who was present, reduced it in the usual manner. The head of the humerus went into the glenoid cavity with an audible snap. By placing the elbow close to the side and raising it over the head, Mr. Wilson satisfied himself that the dislocation was reduced. The shoulder and arm were enormously swollen, insomuch that there was a difficulty in the first instance of determining whether any fracture had taken place, and the defendant when examining the shoulder and moving the arm asked the man if he felt any grating. This was afterwards made use of by the plaintiff's counsel to throw a doubt on Mr. Wilson's diagnosis. The arm was put in a sling, and bran poultices were ordered to reduce the swelling and inflammation. The defendant saw the man the next day and examined his arm. He found that the head of the humerus had slipped out a little, and replaced it. He continued to call on the man frequently for about a fortnight—the shoulder all the time being in its place (as proved by the man's admitted ability to bring his elbow close to his side), and the swelling of the parts gradually subsiding. After this the man attended at Mr. Wilson's surgery up to March 31, on which day he alleges that he called and requested Mr. Wilson to examine the shoulder stripped. Mr. Wilson satisfied himself, by moving the arm about, that the head of the bone was in position, and told the plaintiff that there was no occasion for him to take off his coat. He merely ordered him to continue the poultices and fomentations. Mr. Wilson did not again see the plaintiff. The latter called at his surgery on April 8, but Mr. Wilson was then ill in bed. His housekeeper was desired to tell the man that he could see Mr. Wilson in his bedroom, but the plaintiff declined, telling

her that 'his arm was going on all right,' and that he only wanted some liniment, which was supplied under Mr. Wilson's direction. He did not call again, but on April 12 (twelve days after Mr. Wilson had seen the arm), he went to a Mr. Harding, a surgeon of Stourbridge, who found the arm dislocated. Mr. Harding tried to reduce the dislocation, but did not succeed, although he obtained the assistance of two Messrs. Freer, surgeons of the town. Mr. Harding, it is to be observed, did not communicate with Mr. Wilson. The following day the plaintiff went to the Birmingham Hospital, where Mr. Baker put him under the influence of chloroform and reduced the dislocation. Mr. Baker said that when the arm was put into the cavity he heard a grating sound, and from his examination of the shoulder he had come to the conclusion that a portion of the glenoid cavity had been chipped off at the time of the accident. After the arm had been set by Mr. Baker, it again dropped out, and was again replaced. The man remained in the Hospital thirty days, and it was stated that he would not again be able to use his arm for working with the hammer. These being the facts of the case, the man brought an action against Mr. Wilson, and obtained a verdict with 50*l.* damages, involving, of course, the costs of the suit. Now, the point of interest in this case seems to be the question whether there was or was not a fracture of a portion of the glenoid cavity in addition to the dislocation; and the only evidence in favour of this view was the statement of Mr. Baker, that he heard a grating sound when the arm was restored to the socket of the scapula. But Mr. John Adams, of the London Hospital, who has certainly had sufficient experience in fractures and dislocations, and who gave evidence on the trial, stated "that such a symptom was not uncommon, and he attributed it to the tendons having been ruptured at the time of the accident." But whether the case were a simple dislocation, or a dislocation attended with fracture of a portion of the glenoid cavity, it does not appear to us that the treatment was otherwise than proper; and the unfortunate result was obviously owing to the nature of the accident, and not to the want of skill in the surgeon. We are the more disposed to notice this case, because one of our contemporaries, who ought to defend professional interests, has taken a most ungenerous, if not erroneous view of Mr. Wilson's position, and without having any evidence befre him of any mistake in diagnosis, beyond that which may have been furnished by newspaper accounts, and which unfortunately was ratified by the jury, proceeds to lecture that gentleman on the necessity of detecting a fracture when it accompanies a dislocation into the axilla, and of treating it accordingly. We repeat that there is no distinct evidence of fracture; and whether there was or not, Mr. Wilson's treatment was perfectly correct, and his being condemned in damages and costs was only one of those unfortunate calamities to which our Profession, from the very nature of our calling, is unhappily liable. It is perfectly awful to contemplate the general ruin to which our brethren will be exposed if every case of Surgery which terminates unfavourably is to be submitted to the arbitrament of a jury, however much we may honour that palladium of British liberty. In every case, for instance, of cataract or iridectomy which terminates unfavourably, the operator may be called upon to defend himself in a court of justice, and of course will be liable to damages and costs; so in any unfortunate case of excision of the shoulder, or the hip, or the knee, the same result might ensue; and *a fortiori*, if any unhappy patient were to die (as they often do) after operations for gastrotomy, or ovariatomy, or hernia, the operator might, and probably will (unless the present system be promptly checked), be sent to take his trial at a criminal court for manslaughter.

THE MEDICAL OFFICER OF HEALTH FOR MARYLEBONE.

In consequence of the lamented death of Dr. R. Dundas Thomson, the appointment of Medical Officer of Health to the Marylebone district has become vacant; and from the great extent of the parish, its populousness, and its wealth, there is considerable interest felt as to the person who is likely to be elected in the place of the late distinguished chemist and sanitarian. It appears that, before Dr. Thomson's death, a very numerous body in the vestry had promoted a memorial in favour of Dr. Whitmore, who was a candidate for the office on the occasion when Dr. Thomson was appointed, and who appears, from some reason or other, to be very popular with the local authorities. This proceeding, on the part of certain members of the vestry, gave occasion to much virtuous indignation on the part of one of our contemporaries; but it is now retorted that the step in question was not taken until it was found that an active canvass was going on on behalf of another gentleman, who was favoured by the 'Lancet.' If such has been the case (and we give the rumour only as it has reached us in the newspapers), the indignation is all a sham. But a very respectable memorial, signed by some two hundred practitioners, has been signed and published, expressing, in general terms, the desirability of pledges in favour of any particular candidate being withheld until the claims of all the candidates should be thoroughly and calmly examined. The high character of the gentlemen who have signed this memorial is a sufficient guarantee that they have been actuated only by the most honourable motives, but yet a certain party among the ratepayers do not hesitate to characterise the manifesto as an attempt to dictate to the representative body; and they even allege (what we do not believe) that it has been drawn up in the interest of a particular candidate. That some of the signatures are those of parties who have certain objects in view, we can readily believe; but in case of most of the others, we feel sure that they desire only to see the position of Health Officer of Marylebone filled by a gentleman of distinguished scientific and professional reputation.

MEDICAL MEMBER OF THE METROPOLITAN BOARD OF WORKS.—On Wednesday last the Vestry of St. Mary, Newington, appointed Benjamin Evans, F.R.C.S., their representative in place of E. C. Dermer, Esq., J.P., resigned.

REVIEW OF THE PERIODICALS.

The 'Lancet.'

Dr. J. Russell Reynolds opens the number with a clinical lecture "On Paraplegia," and relates two cases of that affection which recently occurred in University College Hospital. The first case was that of a married woman, aged twenty-eight, who had long suffered from headache, and who also suffered from dull pain and tenderness in the lower dorsal region, and afterwards from vomiting, numbness in the feet and legs, inability to stand, and impairment of the intellect. She died suddenly, before her case had been thoroughly investigated; but after death there was found to be thickening of the cranial bones, injected and calcified meninges, serum in the ventricles, softening of the spinal cord, narrowing of the mitral orifice of the heart, and disease of the mitral and tricuspid valves. The second case was that of a single woman, aged fifty-seven, who was suddenly seized with paralysis of the lower extremities, and, after exhibiting a variety of symptoms indicating spinal disease, died in a few days. On a post-mortem examination a large quantity of healthy-looking pus was found in the spinal dura mater, and this pus was in direct communication with an old abscess in the neck. The suddenness of the attack was, in all probability, due to the passage of pus from the abscess into the spinal column.——Sir J. Ranald Martin communicates a paper "On the Suppurative Stage of Acute Hepatitis," and discusses, at some length, the question of surgical interference in cases where the suppuration tends towards the abdominal parietes. He insists very strongly upon the necessity of an accurate diagnosis being made in the cases which are to become the subjects of operative proceedings, and he states that, whenever the indications are clear as to the existence of suppuration, and as to the site of the abscess, the constitution suffering in the meantime, the sooner the abscess is discharged the better it is for the safety of the patient. Dr. Cameron has shown that both exploration and puncture may be safely and efficaciously employed; and even when no abscess exists, the puncture is not attended with any ill result. When there is an abscess, the discharge of the matter may save the life of the patient.——Mr. Barnard Holt contributes a paper "On the Treatment of Strictures of the Urethra," describing further cases illustrating the benefits arising from the employment of his stricture dilator. The cases are eight in number, and in all of them the results were successful. Mr. Holt considers that his operation may be performed with perfect safety, if surgeons will only insure the dilator being passed fairly through the strictures, and not through the side of the urethra, as has been done, into the bladder. ——Dr. G. F. Bone gives a "Report of a Case of Aneurism of the Abdominal Aorta and of the left Femoral Artery." The patient was a soldier in the Royal Artillery, in which corps Dr. Bone is a surgeon; and the treatment adopted was to prescribe rest in bed, a nutritious, but not stimulating diet, the administration of wine and sedatives, and the local application of a tourniquet over the diseased femoral artery. It appears that these measures were attended with success, for although the man was discharged invalided from the service, he seemed improved in all respects.

'Medical Times and Gazette.'

In the present number there are papers by Mr. J. Zachariah Laurence, "On the Optical Defects of the Eye;" by Dr. Gairdner, "On Auricular-Systolic Murmur; or, the Murmur of Mitral Obstruction;" by Dr. James M'Craith, "On the Use of a Double-edged Knife, with its cutting part bent at right angles, in Operations on the Eye." The paper contributed by Mr. Laurence is the second of the series, and opens by giving the measurements of the eyeball, from before backwards, as being about nineteen-twentieths of an English inch, and by a reference to the soft lenses (the aqueous, the crystalline, and the vitreous), in which it is mentioned that they are altered in various ways by the muscles connected with them. In the distant range of vision these muscles are relaxed, or in a state of tonic contraction, and then the eye is at rest, the lenses being fixed in a certain definite curvature. In this state of the eye, the image of whatever object we behold is thrown exactly on the retina; but if a near object be viewed while the eye is at "rest," there is a confusion of the circles of reflected light, and the object-image falls not *on* the retina, but at the back of that membrane, unless there be an increase in the curvature of the lenses. This alteration of curvature does actually take place in the human eyes, before they can distinctly recognise a near object after they have been viewing a more distant, and was demonstrated to be the case by Young, and by Kramer, through the instrumentality of his phakocidoscope. This "accommodation" of the eye (virtually of the crystalline lens) is quantitive, or, in other words, is one of magnitude. The power of adaptation of the eye is imitated by opticians, who, in the defective visions (near and far sight), correct the imperfections by means of suitable glasses. The power of accommodation varies very much in different persons, in different periods of life in the same person, and in the eyes of the same individual. "Paralysis of accommodation" has been noticed to occur in the course of diphtheria and after an attack of scarlatina, and can be induced by the use of atropine. A young, healthy eye has an accommodation of a quarter of an inch for the two eyes together, and of one-third for one eye used alone. The mechanism of accommodation was considered by Young to be regulated by the crystalline lens, which he supposed to be composed of fibres that, being muscular, were able to contract and relax as ordinary muscles, and so regulate the adaptation of vision. This has been disproved by Kramer and Helmholtz, the former of whom considers the iris as the regulator of the accommodation power. This opinion has given place to that now entertained—namely, that the adaptive power rests in the ciliary muscle, which, according to Müller, Van Reeken, and Rouget, is composed of two sets of fibres, one being circular, the other radiating. The circular have the power of increasing the convexity of the crystalline lens, while the radiating possess antagonistic action. It is the opinion of the author of the paper that the iris has no share in the accommodation process, more than as an auxiliary organ for the improvement of defective vision, and that the action of the pupil—contraction and dilatation—is supplemental to the accommodation. Some suppose the extrinsic muscles of the eye to be the accommodating agents; but this hypothesis is untenable since the power of

adaptation remains even when there is paralysis of all the ocular muscles. All accommodation after the eye has been operated on for cataract is not quite lost; and that which remains is dependent upon a diminution in the aperture of vision whereby the circles of confusion of reflected light are lessened, rather than upon any true power of accommodation. Dr. Gairdner's "Note on the Auricular-systolic Murmur" is called forth by some remarks made by Dr. Ormerod in his "Address in Medicine." Dr. Gairdner is at issue with the opinions expressed by Dr. Ormerod. 1st. The auricular-systolic murmur precedes—not accompanies—the first heart sound and the impulse, and is symptomatic of mitral obstruction. 2nd. This kind of murmur is never "a murmur of palpitation," but is always occasioned by actual organic change; that change consisting in contraction of the orifice leading from the auricular into the ventricular chamber. 3rd. Nearly all alleged mitral murmurs with the second sound are really auricular-systolic preceding the first sound, or prolonged into the first from the second sound and engaging the period of rest. 4th. Dr. Gairdner states that the auricular-systolic and the ventricular-systolic murmurs are very frequently combined in the same case, and that Dr. Ormerod's explanation of the cause of the murmur in question cannot be accepted as correct. Dr. James M'Craith, of the British Seamen's Hospital at Smyrna, shows the "Use of a peculiar-shaped Knife in Eye Operations." The instrument was (Dr. M'Craith conjectures) originally intended to be used in extraction when that operation is practised at the superior part of the cornea, in cases where the ordinary cataract-knife could not be used on account of the entire eye being deeply sunk. An interesting case is brought forward, in which Dr. M'Craith opened with the peculiar knife he describes the cornea at its upper part, where alone it was clear, drew out the iris by means of a toothed Assilini's forceps, cut off a portion of that curtain, and formed an artificial pupil: subsequently cataract was found to exist, and the lens was, therefore, broken up by means of cataract needles passed through the cornea. The best possible success was attendant upon the operation.

OBITUARY.

R. D. THOMSON, M.D., F.R.S.L. & E., F.R.C.P.

We regret to have to announce the demise of this gentleman on the 17th inst., at the residence of his brother, Dunstable House, Richmond. Dr. Thomson was born in the year 1811, in the parish of Eccles, in Berwickshire, of which his father was minister. He was educated for the Medical Profession in Edinburgh and Glasgow. In Glasgow he studied chemistry under his uncle, Dr. Thomas Thomson, then Professor there; and in 1840 he was at Giessen under Liebig. After making one voyage to India and China in the service of the East India Company about 1835, he settled as a Physician in London, and took an active part in the establishment of the Blenheim street School of Medicine.

At an early period of his career he applied his chemical knowledge to the investigation of a variety of physiological questions—the composition of the blood, especially in cholera, amongst others; and he soon made himself a reputation as a correct and philosophical observer. He was employed by Government to make a series of experiments on the food of cattle, and to analyse the water supplied by the different London companies. His researches on the constituents of food in relation to the systems of animals have long been a standard source of reference for physiologists pursuing similar inquiries, and have served as a basis for much of the progress of modern dietetical science. They had extended circulation amongst the scientific world here, and passed through two American editions. In 1841 he went to Glasgow as an assistant to his illustrious uncle, the Professor of Chemistry, whose failing health required assistance, and who died in 1852. Dr. Thomson was unsuccessful as candidate for the chair and returned to London, where he was appointed Lecturer on Chemistry to St. Thomas's Hospital; and when Medical officers of health were appointed under the Metropolitan Local Management Act, he was the successful candidate for St. Marylebone. This appointment was admirably fitted to bring out his abilities. He devoted himself with great zeal and industry to the organization of a system of inspection in that extensive parish. In this difficult undertaking he was so successful that his colleagues were glad to follow in his steps; and when they formed themselves into an Association of Health Officers they ultimately appointed him their president. Dr. Dundas Thomson took always a leading part in the discussion of sanitary questions, as he was qualified to do; and the position which he held among his compeers in the metropolis was worthy of the great borough which he represented. From his position as a health officer he became widely known as an authority on sanitary matters. He was employed by the Registrar-General to make a monthly report of the amount of impurity in the waters of the different London companies.

For the last two years his health (long robust) had begun to fail, but it is only within the last few months that his friends have felt seriously uneasy. For more than a month he was unable to leave his room, and he expired on Wednesday morning at eleven a.m.

Dr. Thomson was loved and admired by his friends; and his conduct as the health officer of the largest parish in the metropolis commanded the respect of the public, who are indebted to him for services which are not yet fully appreciated.—'Lancet.'

LEGAL INTELLIGENCE.

RECEPTION OF AN ALLEGED LUNATIC INTO AN UNLICENSED HOUSE.

BOW STREET.—AUGUST 18TH.

Mr. Henry Wilkins, of Ealing, surgeon, was summoned before Mr. Henry, at the instance of the Commissioners in Lunacy, to answer the charge of having received a lunatic into his house without a licence, contrary to the provisions of the Act, 8th and 9th Victoria, cap. 100, sec. 90.

Mr. Law, solicitor to the Commissioners, conducted the prosecution; and Mr. Brown, solicitor, of Ealing, appeared for the defendant.

John Haylor, police-constable S 509, stated that he was on duty in the Edgware road at half-past one o'clock on Saturday morning, the 6th inst., when he saw a young woman and a man talking together. The man walked away on seeing the witness. About twenty minutes afterwards, after going round his beat, he saw the woman again at the same spot, and asked her what she was doing there at so late an hour. She replied, "I often take a walk in the evening." The witness asked her other questions, but her answers were so strange and incoherent that he could not comprehend her, and he felt it his duty to take her to the Portland town police-station. She muttered something to the inspector, and at his request wrote down her name and address as "Eliza Mitten, Dr. Wilkins, Ealing green." As both witness and the inspector considered her to be of unsound mind, she was taken to the Marylebone Workhouse, and placed under the care of Dr. Fuller. It was then about twenty minutes past three in the morning.

Mr. F. Fuller, resident surgeon of the Marylebone Workhouse, deposed that he placed the young woman under the charge of the nurse in one of the lunacy wards, directing that she should be put to bed and closely watched. He considered her insane. At about eleven o'clock the same morning he directed Dr. Randall's attention to the case.

Cross-examined.—I directed no medical treatment. I considered her insane from her general manner. She muttered to herself, wanted to go away, talked incoherently, and looked into an empty fireplace to see if there was a fire.

Dr. John Randall, 14 Portman street, Portman square,

physician, stated that he occasionally attended at the Marylebone Workhouse. He saw Eliza Mitten there. She appeared about twenty-five or thirty years of age, but he could not ascertain the fact from herself. Mr. Commissioner Wilkes happened to be present, and they both examined her in reference to her state of mind, and were so satisfied as to her insanity that he told the Commissioner he would apply for an order, and send her to an asylum the next day. While he was at the workhouse with Mr. Wilkes, the defendant arrived there. He came to witness's room and said, "You have got one of my patients here." He gave his name and address, and said that he was a medical man, adding that the girl had escaped from his house. Mr. Wilkes asked him what kind of lunatic he considered her, and he replied that she was a nervous patient, and had escaped before from his house.

Defendant.—I assure you I did not say that. You quite misunderstood me.

Witness.—I understood him to say that she was in the habit of escaping. I think his actual words were that she was an "old card" or "old hand" at it. Mr. Wilkes asked him if his house was licensed to receive lunacy patients, and he replied in the negative. He said that the girl had been placed under his charge by her father.

The defendant repeated his denial of the witness's statement, and said he distinctly affirmed that the young woman was not a lunatic, but only a nervous patient.

George Edward Douglas, master of the workhouse, proved that the defendant applied for the young woman as one of his patients, and indorsed the entry in the porter's book recording her admission into the house with an acknowledgment that she had been delivered up to him. He then, with the sanction of the medical officer, took her away with him. The witness understood him to say that Miss Mitten escaped from his house at about one o'clock, and was traced as far as Kilburn gate.

Mr. W. Mitten, of Stamford, said he was the father of the young lady in question. Owing to her general ill-health he had placed her under the care of Dr. Wilkins about two years ago, stipulating that she should be treated as one of his family. The doctor who had attended his family had advised him to send her away for change of air, and he agreed to pay Dr. Wilkins 180*l.* a year for her maintenance and medical attendance. She was still residing with the defendant.

By Mr. Brown.—My daughter has corresponded with her sisters and myself since her residence with Dr. Wilkins. I have never known her to be under personal restraint. She is not a lunatic, and I have been much surprised to hear her so described to-day. She is of a nervous and excitable temperament. The receipts given by defendant for the money paid to him are made out "for board and attendance."

Mr. Henry.—Is your daughter here to-day?

Witness.—I believe she is not.

Mr. Henry.—Is there any reason why she should not attend?—No answer.

Mr. Brown said he had considered that it would be very undesirable to bring the lady into court to hear herself called a lunatic. The excitement of an examination might do her much injury.

It was admitted by the defendant that he had no licence to receive lunatic patients.

Mr. Brown then addressed the Court in reply to the charge, which he denounced as a monstrous perversion of the Act. It was a very common and a very wise practice to intrust persons of sickly health entirely to the charge of a medical man, and, looking to the position and respectability of the defendant, he considered the charges made for the board and medical care of this young lady extremely moderate. Even if she had suffered from temporary aberration of mind on the night in question, aggravated as it must have been by her removal to a lunacy ward, and her examination by lunacy doctors, there was not a tittle of proof that her mind was in the slightest degree affected when she was first received as a patient into the defendant's house. Unless a fact of this kind were established, the magistrate would have no jurisdiction.

Mr. Henry said he must send the case for trial, and then if the defendant thought it expedient to produce the young lady herself, the jury would be the better able to pronounce a judgment as to the state of her mind.

The defendant was admitted to bail—himself in 60*l.* and two sureties in 30*l.* each.

CENTRAL CRIMINAL COURT.—AUGUST 18TH.

OLD COURT.

(Before Mr. Justice BYLES.)

Edward Pope, twenty-two, described as a labourer, was arraigned on an indictment charging him with feloniously and maliciously sending a threatening letter to Mr. William Chapman Begley, threatening to kill Sir George Grey, the Home Secretary, the said William Chapman Begley, and "a certain other person therein named."

Mr. Giffard and Mr. Beasley appeared as counsel for the prosecution, which was instituted on the part of the Crown; the prisoner was undefended by counsel.

On being called to plead, the prisoner replied in an emphatic manner, "I wrote that letter."

Mr. Giffard submitted that the prisoner was not in a fit state of mind to plead.

A jury was thereupon impanelled to try the question of his sanity and his capacity to plead.

Mr. John Rowland Gibson, the surgeon of the gaol of Newgate, deposed that the prisoner had been under his supervision since the 22nd of July; that witness had conversed with him daily; and that, in his opinion, he was of unsound mind, and not in a fit condition to plead or to do any other important act in life.

Dr. Begley, physician of the Hanwell Lunatic Asylum, said the letter in question was addressed to him and sent by post. He had seen the prisoner that morning, and also on Monday morning, and he agreed with the previous witness that he was of unsound mind. The prisoner was admitted to the asylum in July, 1863, and was discharged as recovered in May last. The offence was committed on the 14th of July. He laboured under the delusion that he was the Prince of Wales, and was in the habit of writing threatening letters to his Royal Highness denying that he was the Prince of Wales. He had, however, recovered from that delusion for at least five months before he was discharged.

Mr. Justice Byles, addressing the jury, explained that this was an interlocutory proceeding, and that by the common law of the land, independently of any statute, a man who was of unsound mind, and not able, for example, to challenge the jury or to plead, or to judge of the evidence, could not be put upon his trial. Even if he had a counsel and appeared to be of unsound mind when called to plead he ought not to be tried; and by the common law the judge was empowered to impanel a jury on the spot to decide upon the state of his mind. That had been the common law for centuries, and had been recognised by a statute passed sixty or seventy years ago. Further, if a man became a lunatic between verdict and judgment judgment could not be passed upon him, for the English law, in its tenderness towards persons charged with offences, presumed that he might have something to allege why sentence should not be given, and even if the lunacy arose between judgment and execution execution could not follow. But as it was easy to feign madness the question was always submitted to a jury. The prisoner, it appeared, was under the delusion that he was the Prince of Wales, and was a dangerous lunatic, but all the jury had then to say was whether he was fit to take his trial. Their verdict would not decide that he might not be brought to trial a year after. On the contrary, he might be called to account for what he had done whenever it might please God to restore his intellectual faculties.

The jury returned a verdict that the prisoner was of unsound mind and incapable of pleading.

Mr. Justice Byles thereupon directed that he be kept in custody during Her Majesty's pleasure.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—The Library is closed from Monday, the 15th inst., to Saturday, September 10th, both days inclusive.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JULY 6TH, 1864.

DR. OLDHAM, PRESIDENT.

(Continued from page 107.)

Dr. GRAILY HEWITT considered the principle enunciated in the paper now read, of the necessity of interference in cases of placenta prævia, to be one of great value. This principle had never been sufficiently insisted on, and although admitted by men of experience, it had not been laid down as a principle in the obstetric text-books. He might mention that two years ago a gentleman in practice in Yorkshire had, in conversation with him, alluded to this very subject, having lost a patient from a suddenly recurring hæmorrhage, due to placenta prævia. The gentleman in question had hesitated, on the occurrence of the first hæmorrhage, to induce premature labour, not finding such practice sanctioned by the text-books, and the patient, living at some distance, had perished when the hæmorrhage recurred two or three weeks later, before assistance could reach her. Doubtless there were cases of this kind occurring from time to time, and which would have been saved by interference. He considered, therefore, that the expression of the opinion of the Society on this subject would have a most beneficial influence, and that the patients known to have placenta prævia would not be left liable to perish at any moment from hæmorrhage. With reference to the particular plan of treatment advocated by Dr. Greenhalgh, which was a modification of the "plugging" system, he had some remarks to make. It was to be recollected that in cases of placenta prævia we have two lives to consider—that of the mother and that of the child. What is best for the one is not always the best—nay, it is frequently the worst—for the child. The safety of the child lay in speedy delivery; the safety of the mother in preventing hæmorrhage. Plugging the vagina, artificial or partial separation of the placenta, were measures calculated to stop hæmorrhage; but such treatment, unless accompanied with speedy delivery, was prejudicial to the child, whose vitality was necessarily destroyed by separation of the placenta to any considerable extent, with or without concurrent external loss of blood. On referring to Dr. Greenhalgh's statistics, it would be seen that although the mortality to the mother was, on his system of treatment, low, yet that the percentage of still-births was high, and the plan in question was, therefore, open to this serious objection. He (Dr. Hewitt) was quite aware that it was impossible to legislate equally well for all cases, the circumstances of each case being, to a great extent, peculiar; but any generally accepted system of treatment must have in view the preservation of the lives of both mother and child. Rapid natural delivery best fulfilled all the indications, and this should be the object sought to be attained in the treatment of these dangerous cases. In a certain number of the instances rapid natural delivery was not possible, and under these circumstances the operation of turning offered the best alternative. The extraction of the child should not be performed too soon after the version, unless the bleeding still continued; for until the os was tolerably dilated, the neck of the child was likely to be so tightly caught by the os as to prevent extraction. When the fœtal heart was beating very slowly, rapid extraction of course afforded the only chance of preserving its life. In conclusion, he considered the Society under obligation to Dr. Greenhalgh for his very practical and able paper.

Dr. BEATTY (of Dublin), in reply to an invitation from the President to address the Society on the subject, said that he addressed the Society under very serious difficulty; for not having had the advantage of hearing the paper now under discussion read at the former meeting, he did not well understand its bearings; but as well as he could collect from the speakers who had preceded him, he inferred that there were two points particularly dwelt upon by the author. The first was the *time* at which we should interfere in cases of placenta prævia; and the second, the *kind* of assistance most proper to be given. It appeared to him (Dr. Beatty) that the author of the paper recommends delivery as soon as possible after the case was fully made out. In this respect there was not much difference between his and the practice very usual in Dublin. We wish to finish the case as soon as possible; but it must be recollected that in many cases speedy delivery was impossible, for occurring as the hæmorrhage most usually does for the first time in the eighth month, or even earlier, when the os uteri was little disposed to relax, it not unfrequently happened that the os uteri was so rigid that delivery could not be attempted. We must then temporize, and by means of position, plug, cold, &c., endeavour to gain time, and save the patient from loss of blood as much as possible. He had spoken now of cases in which there was complete covering of the os uteri by the placenta; but in cases of partial covering, where we could feel any portion of the transparent membranes, the practice was to rupture them at once, and discharge the liquor amnii. When this could be accomplished, we feel pretty easy about the case. The head of the child comes down, and, by pressure on the placenta, prevents any further loss of blood. If the uterus was not disposed to act vigorously, its action was quickened by the ergot of rye. He always depended upon the infusion of the powder made on the spot. It was a medicine that required great care for its safe preservation. He never went out without a drachm of the powder in his pocket-case. It was put up in metallic paper, so as to prevent the absorption of the oil by ordinary paper. It should not be kept more than two months in the case. If not used before then it should be replaced by another drachm. When used it was infused in four ounces of boiling water, and half of it, powder and all, given at once, and the other half in a quarter of an hour. When treated in this way the medicine had never failed him. If the case was one of complete covering of the os uteri, we watch the earliest moment at which the os uteri was dilatable, and then proceed to deliver the patient by turning the child. From these few hurried observations, it appeared that the practice in Dublin does not much differ from that laid down by the speakers who had preceded him (Dr. Beatty) in this debate.

Dr. WOODMAN mentioned some cases in which he had observed the good effects of the treatment recommended by Dr. Barnes.

Dr. GERVIS remarked that the observations of Dr. Beatty relative to the frequent necessity of "temporizing" in cases of hæmorrhage from placenta prævia, where there existed a rigid condition of the os and cervix, illustrated the main point at issue between Dr. Greenhalgh and Dr. Barnes. Dr. Greenhalgh in such cases advised the use of the vaginal plug, an abdominal bandage with which to maintain pressure on the uterus externally, and the administration of ergot; while Dr. Barnes maintained that his cervical dilators by themselves efficiently superseded the use of the plug, the bandage, and the ergot, inasmuch as while they were dilating the os and cervix, they simultaneously prevented hæmorrhage and excited uterine action. In this estimate of their utility Dr. Gervis entirely concurred. Instead of temporizing in any manner, or trusting for the accession of labour to the use of ergot, by these bags you obtained full control of the case from beginning to end; and after adequate dilatation of the os, you could either separate the placenta from the orificial zone, rupture the membranes, and then, if that sufficed to check the hæmorrhage, leave the case to nature, or by the bimanual method of version complete it at will. It was not, of course, meant that the dilators were always needed; but their particular value appeared in those cases where but for their use mere temporary measures had to be adopted until the os had sufficiently dilated to permit of operative procedure, and so possibly lead to a delay that might prove fatal.

Dr. OLDHAM also agreed that it was important to take steps at once in any case of placenta prævia to accomplish delivery—a plan, he thought, admitted by most practitioners in London, and one upon which he had always acted. However to effect this object, he believed that nothing was more easy or satisfactory than to turn by the plan recommended by Dr. Braxton Hicks, and to bring

down the child into the os. He (Dr. Oldham) had only the night before a case where its application was most satisfactory. He considered the plug, which had been recommended for many years, might be used where the cervix was very rigid, and preventing the introduction of the finger; but its chief advantage was as a provocative of labour, and he doubted if it would be equal to stop hæmorrhage.

Dr. GREENHALGH stated, in reply, that he was very pleased to learn from the several speakers that in these cases they had, one and all, adopted the plan of early delivery advocated in his paper, and mostly with satisfactory results to the mothers, which he maintained was not the course recommended in the standard treatises on midwifery or pursued by practitioners in general. He believed that the great success to the children in his cases was mainly due to not separating either a part or the whole of the placenta from the uterus, to retaining the membranes intact until dilatation of the parts had been effected by the pains and plug, and by avoiding version in cases of head presentation, which entailed more or less risk upon mother and child. He was quite convinced that with these precautions a premature child, whose head was small and easily compressible, stood as good, if not a better, chance of being born alive than a child at term. In allusion to the plug, he stated that some years ago, as mentioned in his paper, he had used an inflated india-rubber bag, but had found it ineffectual in arresting the flow of blood from the vagina, which he had never failed to control, no matter how severe, with the spongio-piline plug. He considered the effects of the plug to be as follows:—1st, to prevent the escape of blood from the vagina; 2ndly, to favour its coagulation in the upper part of that canal; 3rdly, to excite uterine action; and, 4thly, to dilate the passages. The author approved and adopted the practice of rupturing the membranes in slight cases of partial placental presentation, and of turning in certain malpositions of the child; but he said that he had not alluded to this class of cases in his paper. Dr. Barnes having stated that the statistics of Dr. Read were not trustworthy, and that the author of the paper had estimated the mortality to the mothers too high, Dr. Greenhalgh urged in confirmation the results of the practice of the Dublin Lying-in Hospital, and of his own early experience in cases of placenta prævia. In conclusion, he trusted that after the expression of opinion of so many eminent accoucheurs, there could be no doubt whatever as to the propriety of early delivery in these cases, upon which the ultimate safety of the mother mainly depends.

MARRIAGE.

GRIFFITH—KING.—On the 2nd inst., at Donnybrook Church, Ireland, by the Rev. J. Carson, M.A., Dr. G. de Gorrequer Griffith, of Lupus street, St. George's square, London, son of the Rev. James Griffith, M.A., Rathgar, to Frances Harriette, daughter of the late Henry King, Esq., M.D., formerly Surgeon of H.M. 33rd Regt., of Elderslie, Co. Dublin.

DEATHS.

ANDREWS.—On the 6th inst., at St. George's terrace, Canterbury, Thos. Andrews, M.R.C.S., aged 59.

COMELY.—On the 1st inst., at Winchester, G. Comely, M.R.C.S.E., of Headley, near Liphook, aged 35.

GILCHRIST.—On the 4th inst., at Kirkton-bank, Carluke, A. Gilchrist, M.D., Surgeon R.N., on the retired list.

PRATT.—On the 23rd ult., at Bude House, Appledore, Devon, C. E. Pratt, M.D., aged 70.

SIMS.—On the 30th ult., at Winster, near Matlock, Derbyshire, W. H. Sims, L.S.A., aged 52.

HARVEST HOME AT THE STAFFORD COUNTY LUNATIC ASYLUM.—The patients of this institution have enjoyed their annual holiday. Between 200 and 300 of the inmates, of both sexes, sat down to an excellent dinner of old English fare, and the day was spent in various amusements. The whole proceedings were under the direction of Dr. Bower, the medical superintendent, and passed over without a single incident to mar the pleasure of the occasion.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 11th inst.:—James Walbridge Snook, St. Bartholomew's; Joseph William Barrett, Eton, Bucks; James Matthew Lowndes, New Kent road.

The following gentlemen also on the same day passed their first examination:—John Roberts Dunn, Middlesex Hospital; Frederick Marshall, King's College.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their first professional examinations during the recent sittings of the Examiners:—Thomas Beamish, Cork; David A. Burt, Fifeshire; John Burton, Staffordshire; W. Alister Catherwood, Donaghadee; William Charteris, Dumfriesshire; James Clapperton, Queen's County; John Davies, Dublin; Samuel Hague, Ashton-under-Lyne; David J. Jones, Carmarthenshire; John Mitchell, Forfarshire; George B. Murray, Dumfriesshire; Richard O'Brien, Ennis; Henry Patchett, Blackburn; Joseph H. Rockett, Yorkshire.

And the following gentlemen passed their final examinations, and were admitted L.R.C.P. Edin. and L.R.C.S. Edin.:—Wm. Hixon Arrowsmith, Co. Durham; Thomas Mein Austin, Edinburgh; Andrew Brown, Biggar; Cornelius Buckley, Skibbereen; George Lion Carrick, Cronstadt; Alexander Clarke, Campsie; Charles Howard Clarkson, E. Indies; Frank Kennedy Dickson, Edinburgh; William Jackson Elmslie, Aberdeen; William Joseph Hepburn, Dublin; David Erskine Hughes, Edinburgh; Joseph Jackson, Cumberland; Henry Northage Land James, Derbyshire; Thomas Radford King, Sussex; Patrick Kynock, Roxburgh; Edward M'Craith, Co. Cork; Joseph M'Donnell, Roscommon; Donald Macgregor, Perthshire; Austin Huitson Nicholls, Dublin; Thomas James Haines O'Connor, Co. Cork; Henry Black Purves, Kelsoe; William Laidlaw Purves, Edinburgh; Schœdde Robertson, Athlone; Valentine Stone, Brechin; William Ballin Thompson, Kerry; David John Walsh, Co. Cork; Edwin Wheeler, Belfast; Francis Buchanan White White, Perth.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their first professional examinations during the recent sittings of the Examiners:—John George, Carrickfergus; Robert Gilmer, Co. Antrim; James M'Ilroy, Bushmills, Ireland; John Clark M'Nicol, Argyllshire; R. Gilbert Williams, Kinsale; Alexander Young, Portglennie.

And the following gentlemen passed their final examinations, and were admitted Licentiates of the College:—James Montgomerie Alston, Glasgow, Alexander M. Anderson, Perthshire; Robert Anderson, Haddingtonshire; Christopher Patrick Bodkin, Co. Galway; James Brims, Caithness; William Campbell, Fort-William; James Smith Crichton, Arbroath; Robert Oliver Cunningham, Prestonpans; Frederick Daly, Co. Cork; James Charles Foley, Co. Cork; Humphrey Carden Gillespie, Cork; Robert Gunn, Caithness; William Skipton Irvine, Londonderry; Andrew Watson M'Andrew, Orkney; Joseph Richard M'Closkey, Londonderry; John M'Gregor, Caithness; Kenneth M'Leod, North Uist; William M'Neil, Wigtonshire; John Moffat, Isle of Man; Patrick O'Keeffe, Co. Cork; John Orr, Glasgow; Angus M'Kay Porter, Belfast; Cuthbert Henry Robinson, Yorkshire; David William Telford, Co. Antrim; Robert Bremner Thomson, Fochabers; David Arno Smet Thorburn, Florence; George Hogarth Turnbull, Roxburghshire; Robert Wright, Edinburgh.

VIVISECTIONS WITH ANÆSTHETICS.—It has been often said of late that vivisections have not added a single fact to practical physiology or medicine, and that vivisections under chloroform is a trivial matter of not the least moment or consequence. A large and important meeting of the Royal Society was held one evening this month, at which the functions of the parts at the base of the brain were the subject of debate, and were most ably discussed. About a

dozen theories, to wit, of the special function of the cerebellum, were cited and examined in detail, including the supposed combining or co-ordination force of Carpenter and the special function in connexion with the sexual organs of Gall, not one of which functions Dr. Brown-Séquard said was true or had a particle of probability to support it. —The debate in the present instance was a masterpiece of such physiological logic as would please John Stuart Mill. Deductions from Leuret's facts and pathology in the human subject admirably urged by Dr. Sharpey, the eliminative logic of Mr. Lockhart Clark, as to what all the other organs do, *leaving out* the cerebellum—we had Dr. Carpenter also in person defending his theory of the combining influence or co-ordinating power of the cerebellum, and denying that what is "volitional" is the same as what is voluntary—we had Mr. Bowman, Mr. Savory (who so recently adopted the popular idea of the co-ordinating power, &c., and proved the cerebellum to be active in somnambulism)—Mr. Huxley breaking a lance with every one, and several others of equal name; but the upshot of the whole thing that we really know nothing of the function of the cerebellum, and will know nothing till a careful series of vivisections under chloroform be instituted. The experiments must be done with microscopic care while the animal is totally still.—In Italy a similar series of experiments are now going on as to the function of the spleen, and already some unexpected results have been arrived at; but quite an excitement has been got up there by English tourists to put down *all* experiments on animals, this opposition arising from want of information, and persons being led by old prejudices of literature now happily abolished.—Dr. Kidd, in 'Medical Press.'

NEGLECT OF VACCINATION.—At a late sitting of the bench of magistrates at Merthyr, James Robinson was charged by the relieving officer with refusing to have a child vaccinated after due notice had been given him to do so. A mitigated penalty of one shilling, with costs, was imposed. A similar case is reported to have occurred at Kidderminster. In this instance two children in the family were already suffering from the effects of small-pox. A nominal fine was adjudged in this case also, the magistrates hoping it would act as a salutary warning to others.

GAS IN BELGRAVIA.—Dr. Aldis, the Medical Officer of Health for this district, has made a series of experiments during the last quarter on the six gases supplied to this locality. The following table gives the average light in sperm candles:—

	Chartered.	London.	Equitable.
Cannel coal	24·38 ...	23·88 ...	26·07
Common coal... ...	14·31 ...	14·31 ...	14·58

All the gases were free from sulphuretted hydrogen, and were so free from ammonia that on only two occasions was any trace of it perceptible.

DR. BROWN-SEQUARD.—The visit to America of this celebrated physiologist is likely to be converted into a permanent residence there, after having abandoned the positions he had successively acquired in Paris and London. He has just received an appointment to the Chair of Physiology and Pathology of the Nervous System (specialised, we presume, expressly for him) at the Harvard University, Boston.

THE SOCIAL SCIENCE CONGRESS AT AMSTERDAM.—The International Association for the Social Sciences (the headquarters of which is in Brussels, and which held one of its meetings in London contemporaneously with our own Social Science Association in 1862) has fixed its next place of meeting at Amsterdam. The Congress will continue its sittings from September 26 to October 1, and has published a long list of subjects to be discussed in the five sections of Comparative Education, Instruction and Education, Art and Literature, Public Charity and Hygiene, and Political Economy. Letters to be addressed to the Secretary, 20 Rue de l'Enclume, Quartier Leopold, Brussels.

THE FOOD OF CONVICTS.—The following is an extract from the circular letter on Penal Servitude, addressed to the judges by Sir George Grey:—"A notion had prevailed in some quarters that the diet was excessive in quantity and unnecessarily good in quality, and the subject was brought under the notice of the Royal Commissioners, who, upon the evidence before them, did not feel justified in recommending any change, though they advised that experiments should be tried, in order to ascertain whether any reduction could safely be made. In consequence of this suggestion, the matter has since been more fully investigated by a committee of experienced Medical men, appointed for that purpose only, and the result has been a moderate reduction in the quantity of food allowed, both in the stage of separate confinement and in that of hard labour upon public works. This alteration has only just been introduced in practice, but there is no reason at present to doubt that it will be attended with success."

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, AUGUST 25.—*Operations* at Middlesex Hospital, 1 p.m.; St. Mary's Hospital, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; Great Northern Hospital, Caledonian road, 2 p.m.; University College Hospital, 2 p.m.; London Hospital, 2 p.m.

THURSDAY, AUGUST 25.—*Operations* at St. George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Surgical Home, 2 p.m; West London Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, AUGUST 26.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, AUGUST 27.—*Operations* at St. Thomas's Hospital, 1 p.m.; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m.; St. Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Royal Free Hospital, 1½ p.m.; Charing-cross Hospital, 2 p.m.

MONDAY, AUGUST 29.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m.; Metropolitan Free Hospital, 2 p.m.

TUESDAY, AUGUST 30.—*Operations* at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

MR. CALLENDER.—The list has been inserted.

THE GRIFFIN TESTIMONIAL FUND.

To the Editor of the Medical Circular.

SIR,—The following subscriptions have been further received on behalf of the above Fund:—

	£	s.	d.
Dr. A. T. Brett, Watford	0	10	6
G. Harday, Esq., Rugby	0	5	0
Amount previously announced . . .	52	8	0
Received at 'Lancet' Office . . .	3	11	0

Yours obediently,

ROBERT FOWLER, M.D.,
Treas. and Hon. Sec.

145 Bishopsgate st. Without,
August 10, 1864.

STUDENS.—Thrombosis signifies a swelling caused by a clot in an artery: embolia is the disintegration of a clot and its conveyance into some vessels at a distance. These significations of the words have been adopted only recently, in consequence of the investigations of modern pathologists.

X. Y. Z.—It is only fair that the results of all the cases should be published, as it is only by such means that a true opinion can be formed as to the expediency and value of the operation.

Mr. M., *Belfast.*—Consult some respectable practitioner in your neighbourhood, but do not pay any attention to the mendacious advertisements in the newspapers. These announcements emanate generally from a gang of swindlers.

Dr. J.—We cannot form any accurate opinion of the merits of the case, until all the facts are laid before us. The extracts alluded to may perhaps throw light on the subject.

THE letter of our Dublin Correspondent shall appear next week.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ON POST-PARTUM HÆMORRHAGE AND ITS SCIENTIFIC TREATMENT.

BY J. LUMLEY EARLE, M.D.,

Obstetric Surgeon to the Queen's Hospital, Birmingham.

(Continued from page 102.)

THE CAUSES, DIAGNOSIS, AND TREATMENT.

Disruption of the Placenta.—In removing the placenta either by traction on the cord or by separation with the hand, a portion sometimes is left behind attached to the uterus. It results, in most cases, from mismanagement, either from premature traction on the cord before the placenta has become totally detached, or from an unskilful and hastily effected separation by the hand. In a few instances, however, a portion of the placenta may be left *in utero* without any fault of the medical attendant. Sometimes a small part of the placenta remains attached to the uterus, while the rest hangs loose in the vagina ; and if the cord happens to be implanted low down, its insertion will be felt with more than usual facility. Most medical men would, in such a case, effect the removal of the placenta by traction on the cord ; and if the attached portion were very adherent, it would be left behind. It shows the importance of making ourselves quite certain of the total detachment of the placenta before proceeding to deliver it by traction, and also of examining it carefully after its removal as a general rule. Then, again, he may meet with a very rare form of placenta, which consists of two separate pieces merely connected to each other by the membranes. Traction on the cord would be very likely to tear through the connecting membranes, and then the largest piece, to which the cord is attached, would come away, leaving the smaller still *in utero*. I have met with only one instance of the placenta being divided into two pieces ; and fortunately the membranes between the two did not break, and both were expelled together. In other cases, almost as rare, a small piece of the placenta may be so adherent to the uterus, that it cannot be separated, and has to be left behind. The hæmorrhage in disruption of the placenta is generally most violent for the first day or two ; then gradually assumes the form of draining ; and about the fourth day the discharge becomes offensive. Sometimes, the flooding does not come on until the third day or later ; usually, however, the discharge from the first is too free. The amount of loss depends a great deal upon the size of the piece retained, and the degree of uterine contraction.

Diagnosis.—If the case has been attended by an experienced practitioner himself, the diagnosis will be pretty easy. There will probably have been some difficulty in the delivery of the placenta, and on examining it a portion will be found to be absent. The uterus externally is more or less *tender* on pressure, and the patient complains frequently of afterpains. A tender condition of the uterus, with flooding soon after delivery, is a most valuable symptom. It indicates that there is a foreign body in the uterus —either a piece of placenta, clots, or membranes. In cases where there have been clots in the cavity of the uterus, I have found that organ sometimes even more tender and irritable to the touch than it is in hysteritis, but, on the removal of the clots, the tenderness has all disappeared, and the uterus could be freely handled. The diagnosis may be more difficult if the case has not been seen for some hours after the accident has happened, especially if the nurse has got rid of the expelled portion of the afterbirth, and the midwife or attendant of the patient, from ignorance of the fact, or from a desire to conceal their want of skill, give us no information which will lead to suspect disruption of the placenta. That the hæmorrhage is due to the presence of some foreign mass in the uterine cavity will be probably clear, from the constantly recurring afterpains and the large and tender condition of the uterus. If the case has not been seen until some days have elapsed, besides the symptoms already mentioned, there will be in addition those resulting from decomposition of the placenta, such as irritative fever and an offensive discharge. The offensive character of the flow may be due to the decomposition of clots or of the membranes, as well as that of a piece of placenta ; but it affords a clue to the proper treatment, as it shows that there is something in the uterus which ought to come away.

Treatment.—The disrupted piece of placenta should be removed at any period after labour, if it can be effected without much hazard to the patient. The earlier the attempt is made after delivery the more likely it is to be successful. In a few hours the uterus may be so contracted that the whole hand cannot be passed into its cavity without risk of injury ; in that case an attempt should be made to remove it by means of one or two fingers. If it cannot be got away, we must then have recourse to means which will restrain the discharge until the placenta is naturally expelled or decomposes away. Ergot is a remedy which I should not give in all cases of this kind. I should certainly administer it, if the contractions of the uterus were weak and far between, but not if the afterpains were very violent and almost without intermission. To restrain the discharge, the following remedies may be tried pretty much in the order stated until success is obtained :—Pressure on the uterus externally, combined with cold freely applied to the abdomen and vulva ; injection of a pint of cold water into the rectum ; intra-uterine injection of cold water ; and compression of the abdominal aorta. If, after the first outburst of hæmorrhage, a slow draining goes on, an astringent mixture may be taken with advantage. Plugging the vagina may be had resort to in cases in which the flooding is serious two or three days after labour, the uterus being pretty well contracted, and other remedies having been first tried and found to succeed only for a time.

Illustrative Cases.

I.—This case was attended by a medical friend about a month ago. It is related in his own words : " S. A., æt. nineteen, married, a small-made healthy-looking girl, was confined of her first child after a lingering labour, owing to the pelvis being rather narrow. After the birth of the child, I as usual passed my hand over the uterus, and found it was contracting fairly. I then made gentle, but firm traction on the cord, having felt its insertion within easy reach of the finger, as well as the mass of the placenta round it. The placenta moved easily halfway down the vagina, and then would come no further. I then let go the cord, and compressed the uterus externally with my hand. After a few minutes, I again made firm traction on the cord, an assistant at the same time applying pressure to the uterus. Feeling the mass of the placenta with the insertion of the cord so far down in the vagina, I used more forcible traction than I would otherwise have done. It then, as if overcoming a slight obstruction, came away with the membranes. Hæmorrhage came on pretty severely, which I succeeded in checking by external pressure and ergot, but only temporarily. The uterus enlarged again, and, as a consequence, severe flooding followed. The hæmorrhage was for a second and third time checked by pressure and ergot, but only for a short period. The flooding had by this time deprived the patient's cheeks of all their colour, and my efforts to stem it having failed, I passed my hand into the uterus and found a piece of the placenta, of the size of half an orange, firmly adherent. Of course, I removed this with my fingers, when the uterus immediately contracted well, expelling my hand, with some clots. From this time, no more loss occurred, and the patient recovered without a bad symptom."

II.—The following interesting fatal case is quoted from Dr. M'Clintock's ' Clinical Memoirs on Diseases of Women,' page 339 :—" This case I saw in the autumn of 1846, in consultation with a practitioner of this city. The patient, a short, healthy woman, was the wife of a butcher, living in the neighbourhood of the Castle market, and had been confined of her sixth child seven days before my visit. The

history I got was as follows:—The child had presented with the feet; hæmorrhage took place soon after its birth; and on introducing the hand for the placenta, this was found so intimately adherent to the uterus, as to render its removal difficult and incomplete, some portions remaining behind. She went on, however, most satisfactorily until the fifth day, when she had a sudden and profuse dash of hæmorrhage, which recurred again and again at intervals At the time of my visit (for I only saw her once), she was much blanched and nearly pulseless, but no discharge of blood was then going on. Late on the afternoon of the ninth day, there having been some loss in the interval, the hæmorrhage broke out afresh with great violence, and before assistance could be obtained she was a corpse. In this instance, it is remarkable that the flooding was the only untoward effect of the retention, no fever or local irritation having been induced. At the time of my seeing her she had a plentiful secretion of milk. I hesitate not to say that this woman's life might have been saved by the timely use of the tampon."

ORIGIN AND NATURE OF SYPHILIS.

By RICHARD SAMUEL SISSON, M.D.

(Continued from page 120.)

Ricord always held that the course of constitutional syphilis had nothing to do with the size, progress, and complications of the indurated sore which precedes it. Everything, he says, depends on the temperament, constitution, or state of health of the patient.

It appears to me, however, that the opinions of Ricord and Acton really amount to the same thing; for, as Mr. Paget states, "the character of the constitutional manifestations depends, like that of chancre, on the peculiar character of the blood."

Bassereau says: "Chancre is, as it were, the touchstone of the constitution. By the action it exercises on the tissues, we are enabled to foresee by what immediate or distant consecutive symptoms it may be followed. When benign, it will announce constitutional symptoms of little gravity; when malignant it will, on the contrary, allow us to foresee that the patient will be affected with consecutive symptoms of a serious nature, so that we can put down as a law the following proposition: Benign indurated chancres are followed by benign syphilitic eruptions and affections of the various tissues, without any tendency to suppuration; indurated phagedænic chancres are followed by malignant syphilitic pustules, and later by ulcerated affections of the skin, suppurating exostosis, necrosis, and caries." ('Traité des Affect. de la Peau Symptomatiques de la Syph.')

It must not be supposed, however, that a patient with benign chancre would necessarily communicate the same benign disease to another. This would equally depend upon the constitutional peculiarities of the recipient, as we might, *à priori*, be led to expect.

Fournier says: "At the time Ricord was delivering his clinical lectures there happened to be a patient in the wards affected with a contagious phagedænic chancre. This chancre had resisted the various medications applied at home, as well as at the hospital. It had destroyed the greater part of the foreskin, ploughed up the corona, on which it had formed a deep groove, and finally carried away one-half of the glans, which was horribly disfigured. . . . I was fortunate enough to inspect the woman by whom this patient had been infected, and I found on the right labium an indurated chancre of about the size of a twenty-centime piece; the base of the chancre presented a well-defined induration. . . . In the course of a few weeks the ulceration was cicatrised. The chancre during its existence never manifested a tendency to spread itself, nor assume the phagedænic form." Both were affected with constitutional syphilis (of what character is not stated). The man was thirty-two years of age, of bilious temperament; the woman, twenty-one, slightly lymphatic. They had been living long together, and were subjected to the same hygienic influences.

Most of the authors I have cited use the term tertiary when describing the last stage of constitutional syphilis. It is badly chosen, since tertiaries so-called are frequently the first manifestation of constitutional infection; and, as generally met with, nothing more, as Dr. Wilks has shown, than the sequelæ of syphilis, or, in other words, the results of a cachexia produced by the syphilitic poison. If the syphilitic virus were present at this stage, we might reasonably expect the same results from contact with the matter of a so-called tertiary sore as obtains from a secondary. All observers and experimenters have, however, agreed that tertiaries so-called are not contagious.

Contagion of Secondary Syphilis.

Ricord followed Hunter in promulgating the dangerous and, as now proved, erroneous doctrine, that the matter of a secondary sore is not contagious. Mr. Acton supports his great master. All these eminent men were, however, misled by the fact that no results followed the artificial inoculation of individuals with the pus of secondary syphilitic sores. We shall see, however, presently, that inoculation artificial and inoculation physiological are not equivalent processes.

Mr. De Meric formerly held the same opinion on these grounds:—He had practised inoculation forty or fifty times with secondary and tertiary pus without any effect, and he was told by Dr. Faye that he had obtained the same results by ordinary inoculation, but had produced an effect by scraping, bathing, and packing up the tissues with the matter. "Indeed," says Mr. De Meric, "I am inclined to believe that if we were to try the pus of cancer, which is well known to be *uncommunicable by ordinary contact* or inoculation, and force it into the system in the manner above mentioned, we might, perhaps, obtain a new and unexpected result."

Mr. De Meric's premises regarding cancer were false, for Dr. Watson mentions instances in which cancer of the penis occurred in men whose wives laboured under the same disease in the uterus; and Mr. Mayo remarks: "No one believes cancer or medullary sarcoma to be contagious;" and that he is fully persuaded from his own observations, as well as from the authority of others, that the matter of cancer or of secondary syphilitic sores introduced into the skin upon a lancet will not produce the disease; but that he and others have witnessed cases of cancer of the penis contracted in the natural way from wives having the disease. The same form of cancer existed in man and wife.

Of the contagious nature, however, of secondary syphilitic sores, the proofs have become so overwhelming, that not only Mr. De Meric, but most syphilographers of the present day acknowledge the fact; but as yet we have no such unanimous opinion with respect to that all-important question—Have the natural secretions of tainted individuals the same contagious power?

Mr. Erasmus Wilson says: "One mode of transmission of the syphilitic poison is that in which a man or woman, having been contaminated by the poison, and having been to all appearances cured of the consequent disease, has, nevertheless, become so saturated with the virus, as to possess the property of communicating syphilis to a sound person, by means of his secretions;" and this mode of transmission he illustrates by cases which have fallen under his own observation. In the following case the infector had never had any secondary manifestation whatever:—

"A young man had a venereal sore which was situated on the inner side of the prepuce. It got well in a few weeks, with the aid of a lotion of sulphate of zinc, and he was not aware of any secondary symptoms having followed in its train. Three years afterwards he had gonorrhœa, which lasted two months; and three years later he married. A fortnight after marriage, the wife, who was a remarkably healthy woman, twenty years of age, applied to me, in consequence of suffering extreme soreness of the vulva, attended with discharge. On making an examination, I found the clitoris and labia much swollen, an abrasion, with a superficial ulceration of the mucous membrane in several places,

and a small quantity of purulent secretion. . . . Secondary symptoms followed."

On the 21st Jan. last, a most interesting paper was read before the Harveian Society "On Indurated Chancre in the Female." The author, Mr. De Meric, related two cases in which the communicants, though labouring under secondary syphilis, had sound organs of generation.—('Med. Circ.,' Feb. 10, 1864.)

But is it possible that such secondary infection could take place without the intervention of a local disease in the recipient; or, as Mr. Mayo puts it with regard to primary syphilis, "are local symptoms necessary at all in syphilitic contagion, or may the poison be directly absorbed without producing any sensible local disturbance at the point where it finds entrance?" "Every surgeon," he adds, "must have met with cases where decided symptoms of secondary syphilis existed, yet in which the patients, where there has been no motive for concealment, have retained no recollection of any antecedent local affection. I conclude that it happens occasionally that a patient entirely overlooks the existence of the primary sore, which heals without the use of remedies. Nevertheless, it is not impossible that the venereal virus lodged upon a surface may make its way into the system without causing a local ulcer at the point where it has found entrance."

"A gentleman," says Mr. Erasmus Wilson, "had a small venereal sore on the prepuce in the month of November. It got speedily well. In the succeeding month of February he suffered from sore-throat and rheumatic pains, but of so slight a nature that he took them to be merely symptoms of a common cold. In the month of June following I was called to see his wife, in consultation with her medical man. She was suffering from syphilitic sore-throat, roseola, &c. She had no disorder of the genital organs, and her husband was free from any symptoms of disease." Mr. Wilson remarks: This is not an isolated case, but I select it from others on account of its freedom from complication, either by time or medical treatment. The primary disease in the husband was slight, but well established; the syphilitic fever or secondary fever was so trivial as to be taken for a common cold; and although the patient consulted his medical man, a relative, on the propriety of marrying under the circumstances, the medical man saw no reason to object;" and he adds: "I apprehend that in this case no one can doubt the natural secretions of the mucous membrane of the husband being the medium of transmission of the poison; and as there was no local disease in the wife, the poison must have been imbibed into her system at once, and thus have contaminated her blood."

Most practitioners must have met with similar cases, which, probably disbelieving their patient's statement, they accounted for in a different way. I have seen several, and was glad to find that the conclusion I arrived at was supported by the opinion of Mr. Wilson.

In his work on syphilis, Mr. Erasmus Wilson has given similar cases of infection, in which, however, the woman was the infector, the man the infectee. The possibility of the one being granted, I see no reason to doubt that of the other.

Swediaur says: "Sometimes, in foul coition, the virus is absorbed by the lymphatic vessels, and directly causes buboes; at other times it seems to pass, immediately after impure coition, into the body, and then produces syphilitic affections in the throat, the skin, and even in the bones, without producing any sensible effect in the parts to which it was at first applied, and that without leaving the smallest trace on the surface of the body. This is what often gives rise to grave errors, into which the physicians often fall, as well as the patient, by supposing the present syphilitic symptoms are owing to some old venereal disease badly cured; though these symptoms may proceed really from a much more recent infection, because they do not think, or cannot even imagine, how it is possible to get the pox without first having had chancres or a hæmorrhage in the genital parts. For the same reason, they are also sometimes disposed to ascribe the cause of their disorder to some perfectly innocent person."—('Syphilis,' vol. i.

(To be continued.

HOSPITAL REPORTS.

By Dr. G. de Gorrequer Griffith.

CHARING-CROSS HOSPITAL.

(Cases under the care of Mr. Hancock.)

Case I. was a bad form of paronychia, or whitlow. The subject of it was a man of about middle age, or somewhat past it, of full habit of body, and of large build. The affection had resulted from a wound of the little finger, where, however, it did not stay its influence, but rapidly extended itself to the hand, and thence to the wrist of the forearm; so that on the occasion of our visit these parts were red, swollen, the skin covering them tense and glazed, and all the other wonted symptoms of involvement of the lymphatics. This condition of the parts was limited to the forearm and the tissues below it; and the elbow seemed to be a boundary, no doubt only temporary, to the morbid action.

Synchronous with all the local disturbance there were, likewise, constitutional or sympathetic symptoms. The tongue was coated with a white creamy-looking fur; the saliva was thicker than it is in health, and with a certain degree of viscidity; the lips were dry; the surface of the body was hot and dry; the pulse on the affected side seemed fuller and to be travelling more rapidly than that in the opposite arm; the water was scanty and highly coloured, and communicated a sensation of heat to the urethra as it passed through that canal; the patient was, moreover, restless and uneasy, and had a feeling of general discomfort.

The treatment prescribed by Mr. Hancock was as follows:—The patient to be kept in bed, and as quiet as possible; the arm bath (which is nothing more than the immersion of the forearm in a vessel of hot water, hot as it can be borne) to be used for the relief of the local disturbance; bark and carbonate of ammonia to be administered internally, as well as a certain quantity of gin and hot water—the former for the purpose of giving tone and strength to the system generally, and for the removal of the depression which existed; the latter to procure a better action of the kidneys, to promote a relieving of any congestion which may have obtained in their blood vessels, and the removal of any obstruction in their uriniferous tubes.

Such were the indications of the treatment to be pursued, and such the objects sought to be obtained.

Case II.—*Elephantiasis.*—This was a case of elephantiasis arabum, or that form of elephantiasis which consists in a hypertrophy of all the tissues,—integument, cellulo-adipose, or connective, muscles, bones,—and at the same time the deposit of a new and altogether foreign and cacoplastic material.

In the subjects of this disease the outer skin will be found to be slightly thickened, while the cutis vera will have become very much so; its structure wholly altered, having been converted into a hard, dense, and rigid tissue, which gives to the affected part its peculiar feel, sometimes brawny, at other times as of stiff old leather which had been well soaked and then allowed to dry slowly and partially, or which had been only partially soaked and then allowed to dry by the process of spontaneous evaporation.

The patient was an old man; was pallid and blanched; emaciated to a great degree; with a peculiar cachectic appearance, and an anxious saddened expression of face; the eyes, sunken; the cheeks were robbed of their fat, were also sunken and hollowed; the entire body was wasted, and was in strange contrast with the enlarged limb.

The disease was limited to the leg, the knee-joint forming the boundary of limitation, and, because of the swelling below it, apparently smaller than the same joint on the opposite side.

Treatment.—Pil. hydrarg. cum scillæ co.; gin and hot water; bark and ammonia; just as in the last case, inasmuch as the indications were the same.

Case III.—*Irritable Bladder and Irritable Urethra.*—The patient was advanced in years and suffered from some of the symptoms of stone in the bladder, of which the most

prominent were frequency of micturition and pain—somewhat acutely felt—after the bladder had been evacuated. The patient was laid on the bed, and when he had placed himself upon his back, Mr. Hancock sounded the bladder accurately, not desisting from his examination till he had fully satisfied his mind that no calculus was present.

The man was ordered a mixture of liquor potassæ, spiritus etheris nitrici, and opium.

This is exactly one of those cases in which we are in the habit of prescribing the bromide of ammonium and with most marked effect, the distress arising from the irritability being rapidly and entirely removed.

We would commend this medicine to the attentive notice of our readers, not alone in the affection of which we are treating, but likewise in all ailments of a similar or nearly similar nature.

CASE IV.—The next bed to which we came contained a patient who was suffering from suppuration consequent on a compound fracture of the leg.

CASE V.—*Compound Fracture of the Ankle-joint.*—In this instance there was some deformity, yet not by any means as much as might be expected from the injuries done to the limb. The man was of the middle period of life, and, previous to the accident, had been of good habit of body. There was a wound on the inner side of the leg, just about the inner malleolus, and from which purulent creamy-like matter flowed pretty freely.

This is exactly a case in which Mr. Hancock—one of the great advocates for preservative surgery — takes especial pleasure, and it was with pleasurable feelings he dwelt upon the interesting features of the lesion before him. Formerly, it was the custom to condemn a limb when reduced to a condition such as that which engaged our attention, and to effect its removal as speedily as expediency and the exigencies of the case would allow ; but now, no surgeon would think of sweeping off a limb, or even part of a limb, because of injuries such as obtained in the present instance, or even of a more serious import ; until, at least, he had used every endeavour and exerted himself to his utmost for the conservation of both the broken parts and the entire limb to which they belonged.

Mr. Hancock pointed out the necessity for strict adherence to this law of preservation, on the ground that the records of surgery furnish a sufficient number of instances where the broken parts, the entire member, and life itself, were imperilled by a fracture ; but where, with most careful watchfulness and treatment, skilful, because based on experience, all were carried through the ordeal of uniting and healing, and in the end restored to their original healthy action.

In the instance before us, the fracture had extended into the neighbouring joint, which was the ankle ; and Mr. Hancock took opportunity to mention that, even were the knee involved in the same manner as was now the ankle, it was imperative upon the surgeon to adopt measures—not for the removal of either the joint so implicated, or the limb to which the injury had been done, and to which the joint belonged—but for the preservation of all the injured parts.

We have *in memory* a case that we saw in Mercer's Hospital, Dublin, under the care of Mr. Butcher, in which there was a comminuted fracture of the lower end of the femur, extending into the knee-joint.

The patient, if we recollect aright, was a young and strong man, of good condition and excellent health, and had received the injury in consequence of the falling of a "stand" at a racecourse.

The limb was immediately, on the patient's admission into hospital, put up in the splint to which Mr. Butcher's name is attached, and was kept in it till perfect union of the broken parts was effected. Recovery was perfect ; and the man afterwards walked with only slight stiffness, from which, however, he ultimately recovery.

CASE VI.—In the next bed was another instance of compound fracture of the tibia. This patient, on the second day after the injury, had been attacked with that peculiar form of delirium called by the names, delirium traumaticum, nervous or irritative delirium, and characterised by a total want on the part of the sufferer of concern as to consequences ; by the flinging about of the limb in a reckless manner ; the tearing away of all kinds of dressing, and by efforts to tear open the wound itself ; by dilatation of the pupils (generally), an anxous, careworn expression of the face which is blanched and cold and often covered with a clammy moisture. The blanching and cold sweat give way during the excitement of the delirium to a redness of the face, and to that kind of perspiration which arises from exercise ; the entire surface of the body is cool, or even cold, and covered with a clammy sweat ; that is, in those moments when the patient is free from the insane excitement, and lies completely passive, and, physically speaking, is at rest ; the pulse, in the hours of quietude, is small, quick, frequent, and sharply strikes the fingers laid upon it ; the tongue is covered with a creamy-white fur and is tremulous when protruded ; the palms of the hands are damp and covered with cold perspiration ; the sensorium is affected, as is evident by the low, muttering delirium which possesses the patient, from which, however, by being addressed, he can be recalled to reason and his proper senses. The tremor attendant upon this form of mental aberration would lead to the supposition that the patient was suffering from the delirium of drunkards ; and this opinion would be confirmed by the other symptoms, among which spectral allusion must be made to occupy a prominent place.

CASE VII. was that of a young man in whom excision of the head of the astragalus had been performed, and that portion of the scaphoid into which the head of the astragalus fitted, and which had secondarily become involved in the disease.

In the first instance, the incision necessary for excision of the joint was practised ; but when a more accurate examination of the diseased parts was obtainable, and their actual condition had been ascertained, Mr. Hancock deemed it advisable to take the first-mentioned steps rather than to sacrifice the entire joint.

The operation succeeded beyond the brightest expectations, and the objects sought to be obtained were being each day fully accomplished.

CASE VIII.—This was a patient who had received a compound fracture of the humerus by the revolution of the arm in a railway-carriage wheel, between the spokes of which the limb was caught and twirled round. There had been some secondary hæmorrhage, not, Mr. Hancock considered, from the main artery, but from the smaller vessels, of which some were probably engaged in the injury done the soft parts.

Mr. Hancock dwelt upon the fact that, in violence done to the limbs, or, indeed, to any part of the body, the vessels, especially the larger, manage to slip themselves out of the way and so to elude any cause which might inflict upon them injury. He also, in the course of some bed-side remarks, related a case that had fallen under the notice of Mr. Guthrie, in which the ball passed through the soft parts covering in and lying subjacent to the vessels, had not injured these latter, but had traversed onward in its course and directly between the two vessels, the femoral artery and vein.

In the present case there was no injury done to the joint, although the fracture had occurred so close to it ; nor did Mr. Hancock anticipate any anchylosis or other abnormal alteration.

The mode of treatment, which we had an opportunity of witnessing, was as follows :—The forearm was bent upon the upper arm at right angles, and was then laid on a well-padded splint, having the same curvature and the same degree of curvature as the arm ; along the posterior surface of the limb there were laid two other splints, one corresponding to the forearm and the other to the upper arm ; besides these, there was another splint — a shorter one —placed along the anterior surface of the arm. All these appliances were held in their places by means of straps and buckles, over which again were wrapped the folds of a calico bandage.

The bone had united, and reparation had also gone on extensively in the wounded soft parts.

CASE IX. was one of femoral coxalgia, occurring in a

child of about five years of age. There was an abscess in connection with the diseased condition of the joint; and, as it had pointed externally, it poured out its contents at the site of pointing, which was in the immediate vicinage of the great trochanter.

As we have in one of our late numbers written a somewhat full account of this affection, we shall not here pause to give the subject a lengthened consideration.

CASE X. was one very full of interest. It was that of a little girl on whom had been performed amputation of the leg immediately above the knee, after excision of the knee-joint had been put into execution, but with want of success.

These operative measures had been deemed necessary because of the ravages of idiopathic disease upon the knee-joint.

Among the out-patients we saw a very bad case of synovitis. The subject of it was a young, strong, active-looking woman: the synovial membrane was immensely distended with fluid, and the patella, lifted altogether out of its place, was found floating at the surface of the distension.

The lesion had resulted from an injury to the articulation.

The treatment carried out in this instance by Mr. Hancock was—first, rest, absolute and complete; secondly, fomentations as hot as ever they could be tolerated; and, thirdly, the internal use of the bark and carbonate of ammonia mixture.

CASE XI.—Also among the out-patients. This was a female cook, who, some little time previously, had been a sufferer from diarrhœa, and who, on the sudden arrest of the alvine discharges, had been attacked with phlebitis of the internal saphena vein of the right leg. The affection had supervened very rapidly, and without any apparent cause besides that just mentioned.

The vein was enormously distended; so much so, indeed, that Mr. Hancock was apprehensive of its bursting at one of those points where it was most prominent, and cautioned the woman (who would not at once come into hospital) that, were such an accident to take place, she should check the bleeding by placing her thumb on the aperture whence the blood would flow. We have said that the vein was distended and prominent at certain points; but, besides these two conditions, it was likewise immensely dilated; was hard, owing to the prominences; presented a knotty appearance. Each prominence seemed to correspond with a valve and to occur in its immediate vicinage. In addition to the above symptoms, there were—heat of that part of the limb along which the inflamed vessel travelled; increased action of the femoral artery, and some pain in the limb, more especially in the immediate course of the vein; there was a sense of general discomfort in the entire leg and thigh, but the amount of pain and local uneasiness, of febrile symptoms, and general sympathetic disturbance were of no great moment, and, in comparison with the magnitude and importance of the local affection, were, indeed, trifling.

Mr. Hancock, in his remarks upon the case, pointed out that the ailment was, in a number of instances, the result of exposure to cold; or, as not infrequently occurred, of the sudden disappearance of the menstrual excretion.

It was not at all unlikely that this woman, from the nature of her employment, had been subjected to the former of these exciting causes. The reasons for the greater frequency of the affection in women rather than in men are, not alone the style of dress worn by them, but also the general comparative delicacy of structure, formation, and constitution, and the difference of action in the sexual functions. All these causes entail a very great susceptibility to the lesion, and, certainly, a very much greater tendency to its occurrence in the female than in the male sex. In the latter we more frequently find the traumatic rather than the idiopathic form of the affection.

We would make one remark before closing these observations, and that is as to the rapidity with which the inflammation is lighted up and the celerity also with which it travels, blocking up as it extends itself along them the vessels it may have invaded.

CRITICAL AND ANALYTICAL REMARKS
ON
THE BRITISH PHARMACOPŒIA.

THE CHEMICAL DEPARTMENT UNDER THE SUPERINTENDENCE OF

H. LETHEBY, M.B., M.A., PH.D., &c.,

FELLOW OF THE LINNEAN, AND THE CHEMICAL SOCIETIES, MEDICAL OFFICER FOR THE CITY OF LONDON, AND PROFESSOR OF CHEMISTRY IN THE COLLEGE OF THE LONDON HOSPITAL.

No. XXIV.

LIQUOR FERRI PERNITRATIS.—This preparation was formerly contained in the Dublin Pharmacopœia only; and the process which was there given for its production is the one now adopted.

It is prepared by putting one ounce of fine iron wire into three ounces of nitric acid, previously diluted with sixteen ounces of water; leaving them in contact until the metal is dissolved, taking care, if necessary, to moderate the action by adding a little more water; then filtering the solution, and adding to it as much distilled water as will make its bulk one pint and a-half.

Operating under these circumstances, the nitrate of the peroxide of iron is at once produced, the reaction which occurs being as follows:—

$$2\,Fe + 4\,NO_5 = Fe_2\,O_3\,3\,NO_5 + NO_2.$$

By cautiously treating metallic iron with very dilute nitric acid, and keeping the liquid perfectly cold while the metal is dissolving, it is possible to obtain a solution of the nitrate of the protoxide of iron. Under these circumstances no gas is evolved, but nitrate of ammonia is formed. This change is represented by the following equation:—

$$8\,Fe + 10\,NO_5 + 4\,HO = 8\,(FeO,\,NO_5) + (NH_3\,HO\,NO_5).$$

This formation of ammonia also takes place to a certain extent during the production of pernitrate of iron, and, indeed, whenever metals are oxidised by nitric acid; the metal abstracting eight atoms of oxygen from one of nitric acid and three of water, leaves one of nitrogen with three of hydrogen, which, combined, constitute ammonia.

Proto-nitrate of iron, however, is an exceedingly unstable body, and the slightest alteration of temperature is sufficient to effect its conversion into persalt. In the Pharmacopœia process, the heat generated by the energy of the chemical action at once determines the formation of pernitrate.

It is a most remarkable character of metallic iron that, under certain circumstances, it is unacted upon by nitric acid. A piece of clean iron wire, for instance, may be introduced into strong nitric acid, and probably no action whatever will occur. The iron will remain in contact with the acid without the slightest solution or a bubble of gas forming, but on the addition of a quantity of water violent action will at once set up. When the iron refuses to assume this "passive" condition, as it is called, it may generally be established by touching the metal with a rod of platinum.

Pernitrate of iron, in its ordinary condition, is uncrystallisable, and cannot be obtained in the dry state. Its solution, moreover, is very apt to deposit sub-salt. Liquor ferri pernitratis is described in the Materia Medica as a clear solution of a reddish brown colour, slightly acid and astringent to the taste, giving a blue precipitate with ferrocyanide of potassium. When to a little of it, placed in a test tube, half its volume of pure sulphuric acid is added, and when a solution of proto-sulphate of iron is poured on, the whole assumes a dark brown colour. This test indicates the presence of nitric acid, and thereby proves the salt to be a nitrate. The liquor has a specific gravity, 1·107. One fluid drachm, treated with an excess of solution of ammonia, gives a precipitate which, when washed, dried, and incinerated, weighs 2·6 grains. It gives no precipitate with ferridcyanide of potassium. This character indicates the absence of any proto-nitrate.

FERRI PEROXYDUM HYDRATUM.—Following the example of the Dublin and Edinburgh Colleges, the British Pharmacopœia orders peroxide of iron to be kept in two condi-

tions—the one as a dry powder, and the other as a moist, pasty precipitate. These are distinguished by the names peroxide of iron and hydrated peroxide of iron, although in reality they both contain water, and are, therefore, both hydrated.

The hydrated oxide is made by mixing four ounces of the solution of persulphate of iron already described with a pint of distilled water, and then pouring the mixture into thirty-three ounces of solution of soda, stirring well for a few minutes; collecting the precipitate so formed on a filter, and washing it with distilled water, until the filtrate ceases to give a precipitate with chloride of barium. This oxide is to be preserved by enclosing it, without drying, in a porcelain pot, the lid of which is made tight by a luting of lard. The Pharmacopœia adds that this preparation should be recently made.

The chemical reaction which occurs is extremely simple:—

$$Fe_2 O_3, 3 S O_3 + 3 Na O = Fe_2 O_3 + 3 (Na O, S O_3).$$

The oxide of iron so liberated associates itself with water, forming a hydrate which the Pharmacopœia represents as "$2 Fe_2 O_3, 3 H O$, with a variable amount of uncombined water." Whether this variable amount of water can be spoken of correctly as absolutely uncombined is perhaps a little questionable. It is undoubtedly retained by the oxide with a certain amount of force; and while so present the oxide possesses certain properties, which it loses when this water separates. In the moist, recently precipitated condition, oxide of iron is quite gelatinous. It, in fact, then belongs to the class of bodies which Professor Graham has named *Colloids;* and which all possess the property of associating themselves with an uncertain amount of water to form *jellies*, or gelatinous hydrates. In this state, oxide of iron is most freely soluble in weak vegetable acids; and it is in this condition only that it can be advantageously used for the preparation of the scaling salts of iron, such as the citrate and potassio-tartrate. But this condition is not permanent; if the gelatinous mass be preserved in a bottle for some time, it will be found that the oxide of iron and the water separate from each other, and ultimately a fine pulverulent precipitate will collect at the bottom of the vessel, and a column of clear water will float over it. After this separation has taken place, the oxide will no longer dissolve in the vegetable acids, and it will have lost its colloidal character.

It will be observed that the Pharmacopœia directs the solution of iron salt to be poured into the alkali, and not the reverse, as has generally been the case. This is decidedly the best method of operating; it is very important, in order to obtain a pure oxide, that the alkali should be in considerable excess, and this is insured throughout the precipitation by the Pharmacopœia method of mixing. Unless an excess of the alkali be used, the oxide of iron obstinately retains a portion of the sulphuric acid in the form of an insoluble basic sulphate. It will also be found necessary to use distilled water for washing the precipitate, for the alkaline nature of the oxide would occasion the separation of the lime salts from common water and so contaminate the product. The oxide of iron always retains a portion of the alkali used for its precipitation so strongly that it cannot be removed by any amount of washing. It is on this account that ammonia has generally been used as the precipitant. The Pharmacopœia, however, now orders soda—a change which we regard as unfortunate.

The tests given in the Materia Medica for hydrated peroxide of iron are, that it shall be free from grittiness, and leave on calcination about twelve per cent. of peroxide of iron.

FERRI PEROXIDIUM.—This is prepared by placing the moist hydrate in a warm place until it is dry to the touch, and then exposing it to a heat of 212°, until it ceases to lose weight. When so prepared, it will have the composition Fe_2O_3, HO, and it will be a powder of a dull brown colour. Unfortunately, there is a general liking for bright coloured substances, and consequently this oxide is rarely to be met with in commerce. Manufacturers generally calcine their oxide to give it a nicer colour; but by so doing they deprive it of the atom of water it should contain, and thereby greatly diminish its solubility in acids.

PARISIAN MEDICAL NEWS.

ACADEMY OF SCIENCES.—M. Sédillot brought before the notice of the Academy his method of scooping out diseased bone. The object of the procedure is to leave untouched a layer of bone beneath the periosteum, so as to preserve the shape of the limb and the principal muscular attachments, supplying at the same time all the elements of complete future repair by the transformation of the plasmatic cells of the periosteum, and of the hollowed-out osseous structure. The Professor endeavoured to show the superiority of this method over excision performed beneath the periosteum, an operation instituted in animals and in the human subject with hitherto uncertain results. M. Sédillot's experiments on animals have demonstrated to him the possibility of removing one-half, or even two-thirds, of the shaft of a bone, by excavating the medullary duct without injuring the shape, solidity, or uses of the limb, the bone being reproduced with a degree of perfection which up to the present day had never yet been attained.

In a dog, aged ten or twelve years, the excision beneath the periosteum of fifteen lines of a bone was not followed by any osseous reproduction; but one half of the thickness of the shaft of the os humeri was scooped out, and a new and perfect bone has since formed.

M. Sédillot conceives that such strikingly favourable results must encourage surgeons in the attempt to preserve limbs in many diseases which formerly would have been deemed absolutely to require amputation.

The action of tobacco on the heart was the subject of a paper read by M. E. Decaisne.

"In something less than three years," said the author, "I have been enabled to collect in the three parishes of Mello, Cirès-lès-Mello, and Saint-Wast-Lès Mello (Oise), twenty-one cases of intermittence of the pulse, entirely unconnected with organic disease of the heart; in eighty-eight inveterate smokers, nine were at the same time liable to dyspepsia, but the other twelve never complained of any disturbance of the gastric functions; five or six of the patients had for some time noticed the intermissions of the action of the heart, but paid no attention to the symptoms. In seven cases the intermittence entirely disappeared after a month's discontinuance of the practice of smoking. Two of these individuals were subject to indigestion, and experienced no relief in this respect. In nine others slight improvement only was effected. The remaining five I have lost sight of; all were between twenty-seven and forty-two years of age, and were either spinners or quarrymen.

"None of these subjects were affected with organic disease of the heart, and but few were in that state of health which gives rise to functional disturbance of the action of the viscus. In addition, the discontinuance of the injurious habit of excessive smoking restored the circulation to its natural type; I do not therefore conceive that the following conclusions can be considered rash or premature:—

"1st. Excessive smoking induces in some cases what I may term a state of *narcotism of the heart*, indicated by intermittences in the cardiac and arterial pulsations.

"2nd. This irregularity of the circulation may occasionally be removed, if the habit be partially or altogether discontinued."

ACADEMY OF MEDICINE.—Dr. Azam, of Bordeaux, read a memoir on sudden death, caused by emboli in the pulmonary blood-vessels, after certain traumatic injuries. The following were the conclusions of his paper:—

Fractures and contusions may give rise to the formation of emboli, and to suddenly fatal symptoms.

These emboli originate in a thrombus around the veins of the wounded region, consequent on the absorption of extravasated blood.

The thrombus and the antecedent phlebitis are in general latent, but are, doubtless, more common than has been hitherto supposed.

Careful examination of the superficial and of the deep-seated veins can alone prove their existence.

Sudden pulmonary symptoms, such as dyspnœa, hæmoptysis, præcordial pain, syncope, &c., indicate the presence in the lungs of an embolus, and should therefore awaken the surgeon's attention to the condition of the venous system.

In venous disease the concretions are more or less adhesive, the degree of plasticity of the blood being proportionate to the firmness of the adhesions. Fractures in which absolute rest is required are unfavourable to the plasticity of the blood.

General or partial movements, attended with effort, and the application of pressure, may displace embolic coagula.

In cases of fracture or contusion, surgeons should carefully inquire, a fortnight after the occurrence of the accident, whether any latent phlebitis be present.

If any venous inflammation be detected, entire rest, antiphlogistic measures, and alkaline remedies must be prescribed.

M. Ollier forwarded, through M. Velpeau, the particulars of a case of deformed callus, in which the radial nerve was included. The Lyons surgeon resorted to a procedure suggested by the nature of the injury. The callus was exposed, and a portion was removed with the gouge and mallet, in order to liberate the nerve. A complete recovery has been effected. M. Velpeau remarked that the case was without a precedent in the records of science.

An ingenious contrivance to illustrate the mechanism of the human voice was exhibited by Dr. Collongues, who calls it the *pneumonoscope*. It consists in a bust or lay-figure in statuary-pasteboard, with ten apertures on the anterior part of the chest, and two at the back, each bearing the designation of the peculiar breath-sound to be heard in that region. India-rubber tubes issue from the base of the chest, and to these a blower may be adapted, which on pressure gives rise, according to the tube used, to a faithful imitation of every variety of breath-sound in health or in disease.

To produce the rhonchi, prepared mouthpieces, moistened with an albuminous fluid, must be adapted to the blower, and crepitus, subcrepitus, cavernous, sibilous, or sonorous rhonchi may thus be generated at will.

Thoracic fluctuation, and friction-sounds of every degree of roughness, may also be caused by a very simple contrivance.

The most satisfactory mode of ascertaining whether these artificial sounds are correct reproductions of those observable in pulmonary disease was obviously to refer the matter to the judgment of persons thoroughly conversant with the phenomena of auscultation. Messrs. Bouillaud Barth, Trousseau, Blache, Béclard, and many other learned practitioners were therefore consulted by the author, and all have encouraged his efforts by their approbation.

SOCIETY OF SURGERY.—M. Follin presented a patient in whom he had trephined the mastoïd cells for an abscess consequent on otitis of the middle ear. In this case M. Follin discarded all idea of tubercles of the bone or caries, and attributed the osteitis to the propagation of the inflammation from the mucous lining of the throat to the internal membrane of the mastoïdian cells. The symptoms chiefly consisted in deafness, otorrhœa, swelling, and redness of the mastoïd region, and in an amount of pain so considerable as to cause fever and delirium. Twenty-four hours had scarcely elapsed after the operation, when the otorrhœa and pain subsided, and pus was freely discharged from the wound. In the course of a month cicatrisation was effected, and the patient has entirely recovered. M. Follin has twice obtained the same success from the application of the trephine, in similar cases; and M. Forget has also effected a cure in disease of the mastoïd cells, by perforations with the gouge and lenticular knife.

Several procedures are in use for the treatment of hepatic cysts. Récamier's plan consists, as our readers are aware, in the application of caustic potash, for the purpose of promoting the formation of adhesions, and in the subsequent incision of the tumour when the chances of effusion of its contents into the peritoneum have thus been averted. In M. Boinet's method the cyst is opened at once, and an india-rubber tube is placed in the wound in order to excite adhesive inflammation. A discussion took place on the respective merits of these operations, and M. Boinet's procedure was generally considered dangerous. M. Voillemier remarked that this plan is attended with considerable peril, unless spontaneous adhesions can be positively ascertained to have formed.

M. Chassaignac remarked that he had operated in four cases, in which the cyst contained a transparent fluid, and that a cure was effected in every instance.

The first patient was a woman, and the contents of the sac were removed by puncture: the second subject was a farrier; caustic potash was applied, a trocar was inserted through the eschar, and an iodine injection was thrown in. Two other patients had since been treated by him with perfect success; he had in the first instance merely punctured the tumour, and the sac having filled again, he resorted to the injection of iodine.

In addition, a communication on the same subject was received from M. Heurtaux, surgeon of the Hôtel-Dieu at Nantes, who forwarded the particulars of a case of hydatid tumour of the liver, of five years' standing, which was effectually cured by a single puncture with a trocar half a line in diameter.

In order to avert the necessity for any effort in the course of the day, an enema was administered in the morning. The patient was placed on his back, and the trochar was inserted into the tumour to a depth of two and a quarter inches, at four inches from the linea alba, and about fifteen lines from the short ribs, in the spot where fluctuation was most apparent. The instrument was pushed obliquely downwards, so as to prevent its being forced out by the retraction of the sac. In the course of an hour and three-quarters, a little more than four pints of a liquid, presenting a specific gravity of 1·0074, escaped from the canula. It contained perfect echinococci with their hooklets, many broken hooklets, and other fragments of hydatids. Whenever the canula became obstructed, a silver style was introduced, and the tube was at last cautiously extracted, in such a manner as to prevent the passage of even a drop of the fluid into the abdominal cavity. The operator applied his left hand over the tumour, so as to press the integument against the cyst, and hermetically closing the orifice of the tube with one finger, slowly withdrew it from the wound. Pressure was continued with the hand for about ten minutes, when compresses were substituted, supported by the patient himself.

The man kept his bed for forty-eight hours, and five or six days after was permitted to leave his room. Two years have since elapsed and no tendency to a return of the disease has been observed.

This case must of course encourage surgeons to similar attempts. If, however, we may judge from the views expressed by the members of the Society of Surgery, the prevalent—indeed, the all-but-unanimous—opinion of Parisian surgeons is still in favour of Récamier's procedure.—'Journal of Practical Medicine and Surgery.'

CHOLERA IN SHANGHAE.—Cholera has been extremely prevalent at Shanghae, and the number of fatal cases somewhat alarming. The Chinese authorities have taken up the question of sanitary reform, and have ordered the clearing out of the ditches and drains in and around the Chinese part of the city.

WEYMOUTH SANATORIUM.—The annual meeting of this institution was held in the new building on Thursday, the 4th inst. From the address of Dr. Smith, as well as from the report, it may be gathered that the Sanatorium has progressed satisfactorily since its commencement, and that efforts are now being made to render it as nearly as possible a free institution, the payment of each patient to be limited to 2s. or 2s. 6d. per week. About 5,000*l.* will be necessary for this purpose. Towards this sum Dr. Smith has offered the munificent donation of 500*l.* The meeting separated with a cordial vote of thanks to the conductors.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 31, 1864.

THE IRISH SCHOOLS OF MEDICINE.

There is just at present a period of rest in the schools of the Sister country, in which is laid aside the mental labours of both teacher and pupil; it is not, however, the rest of idleness, but a mere cessation of the *heavy* duties of the sessions—summer and winter—in order to recruit the powers of mind and body, and fit them for the determinate efforts which will be put forth during the coming *annus medicus*.

We are well aware that some masters as well as pupils will spend their leisure hours not in mental culture, nor in making any fresh additions to their already acquired stores of knowledge, but will, on the contrary, squander the hours in, perhaps not actual dissipation, yet in sheer idleness—it may be in looking out dreamily, and with no effort of thought, upon the expanse of waters as they lie outstretched upon the sands of some beautiful watering-place; it may be in lolling lazily under the shadowy protection of some wide-spreading tree, or beneath the coverture of a trellised-work arbour. There are some, we say, of both masters and pupils who will thus spend the moments of the recess; and in the case of some of these, the time so spent is the veriest idleness: in the case of others, however, it is far from idleness, and is that form of complete mental rest which is absolutely needed, and which could alone prove beneficial in quieting the excitement of the mental powers, renovating and building them up, recruiting them as far as they can be recruited, giving them their wonted or even a greater tone, bracing them up to that pitch from which they may have fallen by having been for too long a time kept in a state of over-stimulation.

These are the earnest workers of the schools, who, to overcome every difficulty, and to triumph over the obstacles by which they are beset, strain every nerve they possess, and seek to put their talents out to the highest possible interest. They are able, because they seem to be able. But we would call to their minds the words of the Latin poet:—

"Neque semper arcum tendit Apollo;"

would bid them throw off the trammels of the schools, and enjoy thoroughly the hours of the recess by every form of mental relaxation, and by allowing the mind the fullest possible repose.

To the other class, those who are really idlers, we would say, in the words of Dr. Samuel Johnson:—

"Catch, then, oh, catch the transient hour;
Improve each moment as it flies:
Life's a short shadow, man a flower—
He dies, alas! how soon he dies!"

There is a third class of which we have not yet made mention. It is composed of those who have not overtaxed their strength—mental or physical—and who, during the recess, are fully able to enjoy the rest, at the same time that they are in a position to devote some hours of each day to the study of some subject as yet untried by them; it may be one bearing directly upon their Profession, or collateral to it, or else one having no relation to it whatever.

We shall not, however, dwell on this division of labour, nor on this classification of labourers, since such may be made of the members of all schools; but we shall turn attention to the superior excellencies of the Irish School of Medicine and Surgery, not in its individualities, but as one large body—influential, we know, for good on a large number of the members of the Medical Profession, as well as on the general public.

Let the system of education be viewed in every aspect, and we shall find in each department a great deal worthy of commendation, though at the same time there may be something to condemn: as far as our knowledge of the educational system extends, we venture to assert that very much more recommends itself to our favourable notice than presents itself in an unfavourable light.

Let us begin by reviewing the state of the hospitals, the method employed in giving instruction, and the great advantages which the pupil enjoys.

It is not our intention to draw any comparisons between the Irish School of Medicine and Surgery and that of any other country, although we must confess that, when beginning this article, we had it in our mind to adopt such a course, inasmuch as we are convinced that certain advantages do exist and are to be gained by studying in that school. We will only say, that men educated in the Irish School of Medicine ought to be first-class practitioners, possessed of a good sound knowledge of their Profession, and not alone of an ordinary experience, but of an amount of experience which could be obtained only by a determination to acquire rich stores of knowledge, an earnest working in the acquisition of that knowledge, and an availing themselves of those advantages which are abundantly supplied.

The Irish student, whether of Divinity, Law, or Medicine, is, by many persons both in the Profession and among the ranks of the public at large, commonly supposed to be a rollicking, jolly fellow, fond of all the wild sports peculiar to his country, a good lively companion in hours of pleasure, a good boon companion, and an excellent comrade with whom to quaff and enjoy our cups, but not at all to be chosen if we wish to devote attention to any matter requiring deep thought, anxious and weighty deliberations, and fixidity of purpose when those deliberations are made, and a resolute determinateness to act upon these resolves and to continue acting until they are accomplished. But it is very, very far otherwise; and in the names of the Irish students, not alone in the Irish school, but wheresoever they may be scattered, the wide world over, we deny the truthfulness of such assertions, and with contumely for such opinions—we reject them, knowing them to be based on false premises, and to be erroneous and false deductions from erroneous and false premises.

We shall now give a sketch of the system pursued in the

Irish hospitals—a system which, in duty we are bound to say, must claim the attention and admiration, for its superior excellence, of all who are acquainted with its thorough workings.

It is presupposed by the hospital staff that the student who comes to work at hospital practice has gained some insight into the mysteries and intricacies of his future vocation; that he has begun to lay a good foundation by acquiring knowledge of the technicalities and commonisms of the work he has taken in hand; by gleaning some information upon such subjects as anatomy, physiology, chemistry, and pharmacy; by being acquainted, though not conversant with, the outlines of Medicine and Surgery, the names and terms applied to natural actions and bodies, to various forms of lesions, deviations from nature, and the different corrigents and appliances employed.

With this presupposition, the members of the staff address themselves to the duty of drawing aside the curtain of difficulty which envelops the studies of the novice, and of unveiling the hidden mysteries of the things which belong to Medicine and Surgery. At first the student is perplexed; as, however, subject after subject is unveiled, he becomes dazzled and astonished; then, as his knowledge is extended, perplexity and astonishment disappear, and the vision of his mind is no longer dazzled by the excesses of beauty and the completeness of perfection which he discovers in all the workings of Nature—and that, too, of Nature fallen from her primitive conditions of perfection and glory.

As the mind expands under these genial happy influences, it becomes stronger, is more fully able to recognise and appreciate the intrinsic value of each subject to be learned, or that may have been learned already, and to retain the information it daily acquires.

The first year's attendance of the student at the hospital is recommended by his teachers to be spent in diligent application to the duties of the dispensary attached to the hospital, and in making himself thoroughly—as thoroughly as he can in the brief time allowed him for their study—familiar with all forms of disease as they present themselves among the out-patients.

In some of the hospitals the out-patient work is done before the hour for the hospital rounds has come; and thus the student is not puzzled and annoyed by debating with himself, whether he will continue at the dispensary, or go round with the hospital visiting surgeon. This order, when strictly observed, is really a great boon to the earnest worker, to that student whose sole object it is to study disease accurately and faithfully, not alone in its various forms, but in its alternations—and they are constant—as the disease advances towards health, or retrogrades towards chronicity, confirmed ill health, or, haply, even death.

In the dispensary are practically learned all the minor details of Medicine and Surgery.

When the out-patients are seen, then the students can visit the wards of the hospital, and there, again, are presented to him most of, if not all, the ills of life; and with this presentation comes another, namely, the opportunity to learn the phases of these different ailments; each phase often so diverse from the other, that each, to a casual observer, would seem a distinct affection.

The student is now going round the ward with the surgeon of the day, and his mind is wholly absorbed in the cases before him; nor is it at all disturbed by the apprehension that Dr. Medicine is paying his visit to the patients in the Medical wards, and that Mr. Other Surgeon (than the one with whom he is going round) is operating in the theatre, and that so he is losing the value of Dr. Medicine's remarks, or of Mr. Other Surgeon's manipulalations. The student's mind is engrossed in the work before him, and with pleasure he is either listening to the BED-SIDE instruction which is being communicated by the experienced surgeon, who, having the subject of his clinique—no, we shall keep to the use of our own language, for we detest the introduction of foreign names to garb our ideas, when we can far better express our meaning in our own language,—or, as we prefer it, of his bed-side observations before him, accurately points out important features of the case, and illustrates them by the manifestations as presented by the sufferer. To these he is listening, or else he is reading aloud, for the information and instruction of the surgeon and the members of the class collected round the bed, the history, &c., of the sick person which, when done, the surgeon examines the patient to confirm or rectify the views of the student, and to satisfy his own mind as to the nature of the morbid action, injury, or other cause of complaint. And so from bed to bed both teacher and pupil move; the latter with his private case-book open, ready to dot down anything worthy of note, or to give to the surgeon or to the class any information on any point connected with the case or cases committed to his care. Each student has under him a certain number of cases which belong altogether to himself, and only under the supervision of the resident pupil (if the student to whom the case belongs be a junior), and of the surgeon. The resident pupil corresponds to the house-physician and house-surgeon of the English School.

We think this plan of having cases given into the charge of each student, and having the details of cases taken, not alone by that student, but by the resident pupil, cannot be too highly commended; and we think so for reasons so obvious that we shall not here pause to dwell upon them.

After the rounds and this bed-side teaching have been concluded, should there be time, or any cases upon which more extended comments can be made, the surgeon and the class adjourn to the theatre, and there a further exposition of the disease and all relating to it is made to the pupils.

Thus is spent the first year, or, it may be, the first two years, and then the student passes from the surgical into the medical wards, where the same excellent system of training and teaching is pursued; until, at the end of the fourth year, the student is ready to pass any *practical* examination, almost wholly irrespective of the difficult and searching nature of that examination.

We should mention that it is the custom for posts in the hospital to be given away to the most diligent, and consequently the best educated, of the students who attend it; and, in some instances, are not only given away gratis, but, during the term of their continuance, the student holding certain of them is allowed his hospital practice free, or is not only granted this favour, but likewise is allowed board and lodging for the time he holds office.

There are decided advantages connected with the system pursued at the Irish school. First, the fashion of both physicians and surgeons to pay their round of visits in the morning early, when they and the members of their class are refreshed by their night's rest, and are better able to comprehend the minute details of the patient's condition; and when the patients themselves are invigorated by the repose of the previous hours, or weary and languid from the restlessness in the night watches, or from an exacerbation of fever or pain. It is, we contend, far more beneficial for the student to rescue those clear hours of morning from slothfulness and sleep, and devote them to the practical study of disease, than to the listening to mere recitals of lectures, since the mind is very much better able to embrace a subject in the morning than in the afternoon, when weariness oppresses both it and the body. Again, we think that the patients profit by the early visits of their Medical attendants.

The mode of demonstrating disease by the bed-side, where every part of the discourse can be illustrated by the condition of the living subject as he lies upon his sick-bed before teacher and pupil, is worthy of the highest commendations, since the instruction so given is indelibly impressed upon the attention of the class.

The habit which is inculcated upon the student of keeping a private case-book is most assuredly worthy of imitation in all hospitals.

Then the physicians and surgeons go their rounds on different days: nor do the surgeons attend in the wards at the same time; so that the student need never dread the coming of Surgeon B. while Surgeon C. is going his rounds.

The facts that there are not the breaking-up of large hospitals into a number of small hospital institutions for the treatment of specialities, and that the hospitals which we have designated large are not of such immense dimensions that one loses his way in walking through them, are in themselves properties in connection with the Dublin or Irish school that make these institutions the more valuable to the student, inasmuch as he is the better able to devote attention to all medical and surgical ailments, without having to run from special hospital to special hospital, and to concentrate his mind upon the study of the *comparatively* few cases which can be admitted into hospitals that are very small in comparison with those of other metropolitan towns. This smallness of the hospitals, which necessarily precludes the possibility of admitting very *large numbers*, does not at all imply that there is to be seen *a less variety* of disease or diseases.

Amid all its excellencies, there is one matter which calls for disapproval in the hospital training of the Irish school, and that is the neglect of the use of so valuable an aid to true diagnosis as is to be found in the microscope.

As we are upon the subject of Irish hospitals, there is one institution, the bare mention of which is sufficient to demand from all who have studied beneath its shade an ample share of gratitude for the many and very valuable lessons learned in it, and impressed upon their mind by the teachers who laboured in it. We allude to the Rotunda, or Dublin Lying-in Hospital, which is in no one respect second to any in the world.

REVIEW OF THE PERIODICALS.

THE 'LANCET.'

Dr. GRAILY HEWITT contributes one of his "Clinical Conferences in Midwifery," his present subject being "Difficult Labour from Pelvic Narrowing or Disproportion between the Fœtal Head and the Pelvis." He also describes the treatment, and illustrates the value of turning in such cases. In impaction of the head of the child at the brim of the pelvis, there are four alternatives to be adopted—namely, to wait and see what Nature will do; or to apply the forceps; or to perform the operation of turning; or, lastly, to perform craniotomy. Each of these alternatives is considered; and after showing that all of them have certain disadvantages, Dr. Graily Hewitt proceeds to prove that the operation of turning is, on the whole, the best and safest proceeding, and that, in many instances, it obviates the necessity of craniotomy. Even when there is considerable impaction, the operation of turning may be performed; and although contraction of the uterus is a difficulty, it is not an insuperable one.——Sir RANALD MARTIN continues his paper "On the Treatment of the Suppurative Stage of Acute Hepatitis," and discusses the very important question of making an opening in the liver to discharge the pus. It is admitted that the diagnosis was always difficult and the operation dangerous, but still Sir Ranald Martin thinks that the use of the trocar may often save a patient from certain death. He gives a case in illustration which lately occurred in his own practice, the patient being a gentleman from India suffering from hepatic symptoms, and in whom the abscess appeared to point externally. The exploring trocar was introduced, and pus appeared, and a medium-sized trocar was then inserted and left in the abscess. By this means the pus was discharged, and the patient recovered.——Mr. T. HOLMES continues his *Contributions to the Practical Surgery of the Diseases of Childhood*, his present subject being "Excision of the Hip; with a Report of Eight Cases of this Operation recently performed at the Hospital for Sick Children." Mr. Holmes is not an enthusiast for this operation, but he thinks that in certain cases it is the only means of saving a child's life. At the best, excision of the hip can seldom be a very successful proceeding, as the patient does not generally recover the free use of the limb. The subjects are usually broken down in health by long confinement to bed or by protracted suppuration, and

these circumstances are unfavourable to the process of cure. Mr. Holmes then considers *seriatim* the indications and contra-indications of the operation.——Dr. THOMAS CHAPLIN contributes the commencement of a paper "On the Fevers of Jerusalem," giving some account of their nature, causes, and treatment, as observed by himself in the years 1861, 1862, and 1863. His account of the sanitary condition of the Holy City is sufficiently explanatory of the existence of fevers within its walls. Although the city is on a great elevation and surrounded by deep valleys, the habits of the people are very dirty, the houses are undrained, and the water supply is very defective. Many of the inhabitants are very poor, there is an absence of fresh vegetables, and the food is but little varied. In the present paper Dr. Chaplin describes only the febricula, or mild fever, which is very prevalent, but does not last long, and the remittent fever, which is very intractable, and appears to be caused, in great measure, by miasmatic influences.

THE 'MEDICAL TIMES AND GAZETTE.'

The sixth lecture of "A Course of Lectures on the Urine and Diseases of the Urinary Organs," delivered by Dr. HARLEY to Medical Practitioners, opens the present number. The subject is "Urohæmatin and the Abnormal Pigments met with in White, Yellow, Green, Blue, and Black Urine; their Significance and Treatment." Urohæmatin is the tinting ingredient of healthy urine, and is the great index to the amount of waste which takes place in the human body, as its quantity is exactly proportionate to destruction of blood corpuscles, and is not so much influenced by the diet than are the other ingredients. It differs from murexid in having its colour heightened by the addition of hydrochloric acid, which agent destroys the colour of murexid; also, it is soluble in alcohol. Urohæmatin and blood-hæmatin are very nearly the same in composition. Dr. Harley was the first to extract from urine its colouring principle. Urohæmatin is allied to hæmatin, not alone in appearance and properties, but in containing certain quantities of iron. The properties of this principle of the urine is set forth, the method to be adopted in preparing it, and the analysis necessary for ascertaining the quantity excreted. Lastly, and in conclusion, it is viewed in its physiological aspect.——Under the head of "Original Communications," we find "Clinical Notes and Observations on Contraction of the Fingers, the result of Chronic Rheumatic Affection," by Mr. BULLEY. It is stated that, as a consequence to the rheumatism, the palmar fascia had undergone a gradual condensation, and thus occasioned the deformity. One case is given as illustrative of the author's views, and bearing upon the matter he wishes to impress on his readers. But there is nothing novel in the "Remarks," and we shall not, therefore, make any quotations.——Dr. MONRO relates "Surgical Cases," "Wounds into Large Joints" engaging attention. Two cases are adduced, to show that severe penetrating wounds into large joints do not always demand amputation. In the first case, the wheel of a waggon broke the humerus at the elbow articulation into several pieces, and also made another fracture about an inch above the articulation, the bone at the latter place projecting through the torn integuments. In addition to these injuries, the olecranon process was knocked off, and there was an opening made over it through the superimposed integuments; the radius was broken in its upper third, and there was an opening in the soft parts lying immediately over the external condyle, and communicating with the joint. This patient recovered under the most simple treatment, and at the last examination he was able to flex and extend the humerus, though there was a loss of ability to pronate and supinate. The second case was one in which the right ankle was sprained, while on the left side the astragalus was smashed, and the tibia and fibula fractured about an inch above the joint. The limb was put up in a McIntyre's splint and a liberal diet allowed. A few days after the splint had been applied it had to be removed, owing to excessive pain experienced in the outer ankle, where inflammation and death had already begun their work. A large slough came away and there was left an opening into the joint, which was about the size of a walnut, and which exposed about two inches of the fibula. Turpentine liniment dressings were applied; a good nutritious diet was ordered. That part of the fibula which had been exposed came away in the course of the treatment.—Dr. CHARTRES, Surgeon to the 100th Regiment, reports "A Case of Acute Aneurism of the Aorta," occurring in a young delicate-looking soldier. The symptoms, at first sight, seemed dependent either on a rheumatic attack or upon an ordinary catarrh; the post-mortem examination, however, showed a very large aneurism, the size of an orange, on the transverse portion of the arch of the aorta and adherent to the pleura and thoracic wall, while also it involved the origins of the left common carotid and subclavian arteries as it lay between the innominate artery and the descending aorta. The ascending aorta was greatly enlarged, and its lining membrane had undergone the atheromatous degeneration. Death had resulted from exhaustion.

THE GLASGOW MEDICAL JOURNAL. No. XLVI. July, 1864.

Dr. JAMES DUNLOP, under the head of "Surgical Notes," contributes a paper "On the Restoration to Life of the Apparently Drowned;" and he illustrates his remarks by the history of some cases which he observed in his capacity of Medical officer of one of the Glasgow districts, where drowning, in the Clyde or in the canals, is of rather frequent occurrence. He describes three cases in particular, in which life was restored by the adoption of measures founded upon the plans recommended respectively by Marshall Hall and Silvester. With respect to these two plans, Dr. Dunlop thinks that both have peculiar merits, and that a combination of the two, according to circumstances, ought to be adopted. In inexperienced hands he believes Dr. Silvester's plan to be the easiest in practice; but he condemns that gentleman's recommendation to use the warm bath in cases of apparent death by drowning. ——Dr. T. M'CALL ANDERSON contributes "Some Notes on some Forms of Skin Diseases," his present subject being "Syphilitic Pemphigus in the Adult;" and he asks the question, Is there such a disease? which he answers in the affirmative, and relates a case observed by himself, and alludes to another described by Ricord. In reply to the question as to the mode of determining whether the pemphigus is syphilitic or not, he answers that the syphilitic

disease may be traced as following the contraction of a hard chancre, and may be further distinguished by yielding to antisyphilitic treatment.——Dr. JAMES B. RUSSELL gives an "Analysis of Three Hundred Cases of Typhus," which he attended while he had charge of the fever wards in the Town's Hospital, Glasgow. He found that the cause of the disease was not privation, but bad ventilation and dirt. In the treatment, stimulants were sparingly employed, and the mortality was under the average.——Dr. MCKINLAY relates a "Case of Excision of the Hip-Joint," the patient being affected with scrofulous disease of the head of the femur. The operation was quite successful.——Dr. W. T. GAIRDNER describes "Two Cases of Uterine Tumour, more or less simulating Ovarian Disease;" and he adds some remarks on the diagnosis and on a remarkable action of ergot of rye.——Dr. GEORGE BUCHANAN, of Glasgow, relates "A Successful Case of Ovariotomy," being the first successful case performed in the West of Scotland.——Dr. W. LANG relates "A Case of Poisoning by the Manioc (*Jatropha manihot*) in the West Indies." The case was fatal.——Dr. ROBERT PERRY describes "A Case of Epilepsy," which was fatal; the appearances after death being congestion of the cerebral membranes and extravasation of blood.

THE JOURNAL OF MENTAL SCIENCE, *Published by Authority of the Association of Medical Officers of Asylums and Hospitals for the Insane.* Edited by C. L. ROBERTSON, M.D. Cantab., and HENRY MAUDSLEY, M.D. Lond. July, 1864.

The original articles in this number contain a paper "On the Classification of the Sciences," dividing the subjects grouped under the head of Science into a number of sections, according as they belong to the abstract or concrete or mixed kind: thus, Logic and Mathematics belong to the abstract; Mechanics, Physics, Chemistry, &c., to the abstract concrete; and Astronomy, Geology, Biology, Psychology, Sociology, &c., to the purely concrete.——Dr. HENRY MACCORMAC communicates some "Remarks upon the Ulster Revival, so named, of 1859," and gives some interesting particulars connected with that extraordinary outburst of religious enthusiasm which seized upon so many classes of society at that period. It was, however, confined to members of the Presbyterian and Methodist persuasions, and did not reach the Roman Catholics or the Unitarians. Dr. MacCormac compares the excitement which he witnessed, to some of the recorded outbreaks of religious fanaticism in the middle ages, and he states that many cases terminated in insanity.——Dr. J. G. DAVEY contributes a lecture delivered by him at Bristol "On G. Combe and his Writings," both being highly eulogised by Dr. Davey.——The last original article is "On Unlearning," and shows the necessity of self-culture in developing the powers of the human mind, and in correcting erroneous or imperfectly-formed opinions.——The clinical cases are furnished by Dr. C. WESTPHAL, of Berlin, who relates some cases of "Tabes Dorsalis," and "Universal Progressive Paralysis;" by Dr. T. S. CLOUSTON, who gives some illustrations of phthisical insanity; and by Dr. J. W. OGLE, who details some "Cases of Primary Carcinoma of the Brain, with Observations." The rest of the number is filled up with notes and news on psychological subjects, and a "Quarterly Report on the Progress of Psychological Medicine."

THE SOCIAL SCIENCE REVIEW, AND JOURNAL OF THE SCIENCES. Edited by B. W. RICHARDSON, M.A., M.D. August, 1864.

The Journal opens with a very elaborate article by Dr. EDWARD SMITH, "On Gaol Dietary, and the Operations of the Recent Committees." The question is examined in its chemical and physiological bearings, and Dr. Smith exposes with great power the mistakes which have been made when those who are in authority substitute the results gained by mere experience for those deduced from science; and he defends the views of those who, like himself, have investigated the matter in a philosophical spirit. The rest of this number contains many interesting articles, few of which, however, have relation to Medical subjects, although there is a short notice of the present position of the Army Medical Officers and of their treatment by the Government.

SCIENTIFIC ARTICLES.

POISONING BY STRYCHNIA: RECOVERY FROM A LARGE DOSE.

BY FRANCIS WAYLAND CAMPBELL, M.D., L.R.C.P. Lond.; Physician to the Montreal Dispensary, and Infirmary for Diseases of Women and Children.

The following case is interesting, not only from the quantity of the poison taken, but from the comparatively long time which elapsed before the patient was seen by me, and the consequent delay in the commencement of treatment:—

F—— J——, a gentleman of position in society, owing to reverses in business, had been for some weeks in exceedingly low spirits, and during that time had drank very freely. On the morning of the 17th of November last, he left his house, about eight o'clock, in a very excited state, not having partaken of any food, and shortly after that hour called at a druggist's store and requested one of the clerks, with whom he was acquainted, to give him sufficient strychnia to poison two dogs. About four grains and a half were weighed out to him. He states that he immediately went to a neighbouring fashionable saloon, called for a glass of gin, and placing all the strychnia in it, drank it off. To make sure that none remained behind, he immediately filled the glass with water and drank it also. He then started for home, and on the road one or two very slight spasms seized him. On reaching his house he at once undressed and went to bed, his wife being out at the time. She returned about ten o'clock, and found him in a very strong paroxysm. He at once confessed what he had done, and the family physician, who was sent for, not being at home, I was called upon to attend him. It was eleven o'clock when I reached his house, fully two hours and a half having elapsed since he took the poison. On my entering the room he was seized with a very violent tetanic paroxysm, which lasted fully a minute and a half. He had not vomited, but had drank freely of milk. I at once administered a drachm of sulphate of zinc, which soon produced copious vomiting. When it had in a measure subsided I gave a drachm of tannin in a tumbler of water, which was repeated in about half an hour. A little after twelve another very violent paroxysm came on, which was followed by violent emesis, which continued with a good deal of frequency the entire day. At two p.m. the paroxysms were recurring every twenty minutes, and were very severe. He was given two grains of solid opium, and shortly after drank several cups of green tea. At half-past two, Drs. McCullum and Drake saw the patient, when fifteen drops of the fluid extract of belladonna was injected subcutaneously, near the third dorsal vertebræ. Chloroform was also administered *during* the paroxysm. At three o'clock the spasms were recurring every eight minutes, and very strong, their *duration* being apparently lessened by the inhalation of chloroform. Pulse 130—full and strong. By half-past three the patient began to show evident signs of weakness; the interval between the spasms had decreased to about three minutes, and they were much stronger. Sherry-and-water was given at the rate of an ounce every hour. As the patient was evidently sinking, I determined to try the effect of keeping him partially under the influence of chloroform the whole time. Its effect was all that could possibly be desired. The interval between each paroxysm gradually lengthened, and at seven p.m. it had increased to an hour, though their severity seemed to be but slightly diminished. At this time I had his spine well rubbed with soap liniment and tincture of opium, and gave him a drachm of compound spirits of sulphuric ether, in three drachms of camphor mixture, every two hours, still

continuing the inhalation of chloroform, but not to the same extent as previously. At nine p.m., while drinking some beef-tea, a violent paroxysm came on. Its duration was short, and during the previous two hours he had only two very slight spasms. At eleven p.m., when I left him, no more severe ones had occurred, and only one very slight one. I ordered beef-tea in large quantities, and the wine to be given every three hours. Pulse 120, and weak. At half-past eight a.m., next day, I visited him, and found he had passed a tolerably comfortable night. No spasms—only occasional involuntary twitchings. His spirits are better. To have the ether and camphor mixtures every four hours only. Wine to be stopped. To have beef-tea at intervals, and chicken-broth for dinner. Nine p.m., still improving; the twitchings continue, but neither so strong nor so frequent. From this time the patient made a rapid recovery, and, in a week from the time he swallowed the poison, was out attending to his business. The quantity of chloroform consumed between one p.m. and eleven p.m. was rather more than a pound, and its beneficial effects were certainly most marked. I am firmly convinced that had it not been so largely inhaled the case would have terminated fatally.—'Canada Medical Journal.'

ON THE DIFFERENCE BETWEEN ACTIVE AND ORDINARY OXYGEN.

By M. CLAUSIUS.

Some years ago M. Clausius put forth an hypothesis on the nature of ordinary and active oxygen or ozone bearing resemblance to previous hypotheses proposed by other chemists (notably MM. Favre and Silbermann, Gerhardt, and Brodie), and which he expresses in the two following propositions:—1. Ordinary oxygen is formed of atoms united in binary groups, active oxygen of isolated atoms. 2. The two atoms constituting a molecule of ordinary oxygen are in opposite electric conditions. To these two fundamental hypotheses are added the following accessory hypotheses:—3. The two isolated atoms proceeding from the division of a molecule of ordinary oxygen immediately lose their positive or negative electricity and become neutral. 4. The atoms remaining isolated if a volume of ozone contains the same number of molecules as the same volume of some other simple gas, the density of the ozone should be half that of ordinary oxygen. The third hypothesis is hardly compatible with the existence of antozone, nor with the well-known property of ozone of exercising two opposite actions on oxygen held in combination. M. Clausius, moreover, thinks it better to abandon it. He consequently admits that ozone is formed of electro-negative atoms, and antozone of electro-positive atoms, besides which he thinks it probable that the atoms of ozone consequently retain their electro-negative state, but that the facts as yet known do not authorise so precise a conclusion with regard to antozone. As to the fourth hypothesis, it has become absolutely inadmissible, since the recent experiments of M. Babo and M. Soret have established the fact that ozonised oxygen increases in volume in passing to the state of ordinary oxygen. To reconcile this remarkable phenomenon with his fundamental hypothesis, M. Clausius now supposes that the isolated atoms of active oxygen are able to unite by reason of a feeble affinity between binary molecules of ordinary oxygen; the density of the gas is thus augmented without sensibly diminishing the chemical activity proper to the isolated negative or positive atoms.—'Annales de Chimie et de Physique.'

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, August 18, 1864:—Edward Monro Spooner, Blandford, Dorset; John Lightbody, Kirby Moorside, Yorkshire; Frederick John Cropp, Park road, Clapham, S.; Francis Henry Wickham Taylor, Cottage green, Camberwell; Thomas Henry Greene, Saffron Walden.

The following gentleman also, on the same day, passed his First Examination:—William Harris Butler, Guy's.

REVIEW OF BOOKS.

Treatment of Consumption; with Remarks upon the Properties and Uses of Various Remedial Agents. By Matthew Corner, M.D. Pp. 58. Hardwicke. 1864.

The object of Dr. Corner, as he states in the preface, is to convey to the Profession a method of treatment which he has employed successfully in consumption. On perusing the work, however, we do not find any striking novelty in the plans suggested, and we are by no means disposed to agree with Dr. Corner in the pathological views which he advances. Neither do we agree with him in his therapeutical reasoning, however we may allow that his treatment may have been successful. We cannot admit that he has proved the proposition with which he starts—namely, that phthisis and rheumatism are analogous or identical in their nature; and even if they were so, it does not appear that the circumstance throws any new light on the treatment of consumption. The application of small blisters beneath the clavicles in the latter disease is not a novel suggestion, and we are doubtful as to the peculiar efficacy of bicarbonate of soda or of mercury in arresting the progress of tubercle. We think the following specimen is sufficient to indicate Dr. Corner's views of therapeutics:—"The blistered surface," he says, speaking of the application of blisters in consumption, "acts essentially as a pure derivative; and the benefit produced by it is owing chiefly to the discharge it creates, *bringing the waste matter of the destroyed lung-tissue, composed of arrested cell-growths, broken-down blood-discs, &c., to a part where its presence is less injurious and where it may rapidly be excreted.*" P. 14.

Photographs (coloured from life) of the Diseases of the Skin. By Alex. Balmanno Squire, M.B. Lond., Surgeon to the West London Dispensary for Diseases of the Skin. London: Churchill and Sons. No. I.

Mr. Squire states that, in consequence of the great difficulty hitherto experienced in producing accurate illustrations of the diseases of the skin, he has been induced to try if greater accuracy and more life-like representations might not be obtained by means of photographs of the diseases coloured from life. As far as the present specimen is concerned, his idea has been attended with remarkably successful results; for we can truly assert that a more thoroughly life-like representation than that of *psoriasis diffusa*, presented in the plate before us, we have never seen. It exhibits a perfect resemblance to the original; and if Mr. Squire is equally successful in his forthcoming numbers, he will inaugurate a new era in dermatological illustration. Two pages of letter-press, describing the pathology, appearance, and treatment of psoriasis diffusa, accompany the photograph.

The New System of Musical Gymnastics as an Instrument in Education. A Lecture delivered before the College of Preceptors. By Moses Coit Tyler, M.A., M.C.P. Pp. 32. London: Tweedie. 1864.

The object of Mr. Tyler is to inculcate the expediency of cultivating gymnastics in a novel manner, in which velocity and grace are studied, rather than the power of lifting heavy weights and of performing violent movements, and in which the exercises are regulated in a rhythmical succession by the aid of musical accompaniments. All the muscles of the body are cultivated by this system, the result of which is to produce an equal development of the whole structure, none of the parts being exercised to the neglect of the rest.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—LICENTIATES IN DENTAL SURGERY.—The following gentlemen having passed the necessary Examination, received their Diploma in Dental Surgery on Monday, August 1, 1864:—Henry James Virgin, Oxford; Anthony Percy Reboul, Albert street, Islington; Warwick Hele, Cheltenham; John Clough Clarke, Nottingham.

GENERAL CORRESPONDENCE.

THE SKELETON OF THE GREENLAND WHALE-BONE WHALE.

To the Editor of the Medical Circular.

SIR,—In your number 632, New Series, XXXII., a statement is made that *no complete skeleton* has ever been received in this country of *a Greenland whalebone whale*, notwithstanding the immense number that have been killed by whalers from our ports. I have much pleasure in giving you the following information :—

A finner (a term applied to the young whale by *old* Greenland fishermen) was captured some twenty-five years ago, near Spurn, on the Yorkshire coast, and taken to Kingston-upon-Hull, the entire skeleton of which was placed in the Museum now in Hull. The fish was bought by my father, and through him the Hull Museum became possessors of the skeleton.

I am, &c.,
T. HARRISON MARSHALL, M.R.C.S. Lond.

Chard, Somerset, Aug. 22, 1864.

BEST MODE OF CHLOROFORM ADMINISTRATION.

To the Editor of the Medical Circular.

SIR,—As I am often asked which is the best form of chloroform inhaler, perhaps you would permit me to say, in your practical Journal (in which Journal, indeed, we have always had fair play ; and, as far as London is concerned, have really worked out the great problem of anæsthetics when the other guides threw every obstacle in one's way), that the best form of inhaler is a plain dinner napkin pinned into the form of a cone. It is at once beautifully clean and safe, when the ordinary metal inhalers, one and all, "smell of Bucklersbury," and, not unfrequently, of decomposing organic matter, saliva, mucus, &c., of previous patients who have had the mouth-and-nose piece to the face. An inhaler of card, in form of a cone, used by me, is made by an instrument-maker in Oxford street.

Some unwise writer in the 'Times,' who admits he has had no experience of accidents, is theoretically inclined to underrate the effects of electricity in such accidents. The rest of the letter is made up of practical and supposed original remarks, every one of which I have urged in the MEDICAL CIRCULAR.

Nearly all the doubtful points in chloroform administration are now clearing up—viz., as to inhalers ; as to the dose or quantity ; as to its relative value in dentistry, midwifery, general surgery, &c. ; as to the special patients who ought *not* to take chloroform ; as to the first sign of impending danger ; as to stopping vomiting (so important in eye operations) ; as to the exact value of the pulse ; as to the best mode of restoring life when it has all but become extinct. I have collected 250 deaths from chloroform out of newspapers ; there are perhaps as many more not reported. It seems a great pity the 'Times' should now undo all we have recently been doing as to electricity.

It is not of much use for the journals to be saying now in chorus all the danger is in the mode of administration, or, as at Cambridge, that chloroform is only a deoxygenising agent. How, then, is nitrous oxide an anæsthetic ? or how, as to administration, is the accidental occurrence of increased hæmorrhage at an operation, which turns the scale occasionally against the patient, to be visited on the innocent administrator ? Why should a coroner's jury censure the administrator for a latent idiosyncrasy or such hæmorrhage ? Yet it has been lately done.

I am, &c.,
Sackville street, Aug. 26. CHARLES KIDD, M.D.

DEATH-RATE IN SCOTLAND. — In his report for the second quarter of the present year, the Registrar-General states that, whatever be the cause, the death-rate in Scotland is on the increase, especially in the towns. It does not seem to depend on any particular epidemic, but there is an increased mortality in all diseases. This is not confined to the second quarter of this year, but extends over several years.

OBITUARY.

THE LATE MR. STONE.

We are very sorry to have to record the death of Thomas Arthur Stone, Esq., F.R.C.S., for many years one of the most popular practitioners at the West-end of London. The deceased was son of Arthur Daniel Stone, M.D., Physician to the Charterhouse, and was born in Charterhouse square on March 3, 1797. After receiving his education at Westminster and the Charterhouse, he entered the Medical Profession, and became a pupil at St. George's Hospital. Under the guidance and introduction of his uncle, Sir Charles Mansfield Clarke, to whom he always was most grateful for his unvarying kindness, he entered on the practice of Midwifery and Diseases of Women and Children as a consulting surgeon, and soon attained great eminence and popularity ; but he was averse to specialities, and though he practised as an accoucheur, claimed equal place, as a surgeon, with any of the dignitaries of Lincoln's-inn-fields. He began to lecture on his favourite branch at St. George's Hospital, and his class-room was well filled, but his early and rapid success in practice soon compelled him to give up his chair as a teacher. He was, however, well known among the pupils as a good lecturer, and one who made the lecture hour an hour of pleasing instruction. His practice, in fact, was immense and most lucrative, and brought him into contact with many members of the aristocracy, with whom he had great influence. It must be mentioned, to his credit, that the first-fruits of his professional earnings were devoted towards the maintenance and comfort of his own family. As a practitioner he represented that great London West-end school, of which Halford and Chambers were conspicuous examples. Without denying the great advances which pathology has made in the last forty years, it may be doubted whether anything could be more certain and successful than their practice in the set of cases for which it was specially adapted, and which were to be met with in abundance amongst those amongst whom they practise. There were two instruments which they wielded to perfection, and which, in any civilised and well-fed community, will relieve more than half the relievable maladies met with. One was the thorough purification of the blood by eliciting a copious flow of bile from the liver and intestines ; the other was the relief of any organ suffering under stagnation of blood, by means of local bleedings. It was the writer's good fortune, early in life, to meet Mr. Stone in several cases well adapted for this line of practice, and in which life was saved by resolution and decision at a critical moment, whilst it might have been lost by a temporising and what is called "expectant" method. But whilst eulogising Mr. Stone's great dexterity in wielding these two important therapeutical weapons, we must observe that he thoroughly recognised the alteration which has gradually obtained in prevalent disease, and which has, to a great extent, done away with the necessity of bleeding, these late years, and we must not be supposed to underrate his skill in the use of other remedies adapted for a different class of cases. He was thoroughly conversant with that large class of diseases which Sir Charles Mansfield Clarke first discriminated, and in treating which he and his successors have hardly been surpassed. In fact, in our empirical art, there can be no doubt that the man to *do good*, to relieve the greatest number of unpleasant sensations, and hit upon remedies where the diagnosis is obscure, is the busy practitioner who moves in good society ; and, of this class, Mr. Stone certainly was one—a fact to which his patients have, even since his death, given strong confirmation in letters received from them. In fact, as society is constituted, we may be certain that any man who is in large practice amongst fastidious and sensitive persons, free to choose their own medical advisers, must be able to relieve disease, else his occupation would go from him. If we recollect rightly, Dr. Watson, in his celebrated lectures, expressed his regret that the secrets of such a man as Pennington should have died with him. Equally may we regret that one whose experience was so enormous amongst just that class of cases which students have no opportunity of seeing in hospitals

should have left published no records of his professional opinions. The hospital student sees cases in their advanced and pronounced state, when all pathognomonic signs are developed and diagnosis easy. The practitioner among the higher circles sees cases from the very first uneasy sensations that arise, and before local changes ensue; and has to give his diagnosis, not from the leisurely percussion, auscultation, and measurement, and analysis of secretions of a man lying tranquilly in bed, but from the first feelings of illness which serve as preludes to the fully developed malady; and he has to pronounce, not what is, but what is *coming*. This is a true field for that sagacity which is the fruit of natural acuteness and abundant opportunity of observation, and in that field Mr. Stone was as eminent as he was also distinguished by a genuine, unaffected kindness, which endeared him to his patients. But if he left no published record of his professional work, there is one monument which it will not be easy to efface; and that is, the Charter of the Society for the Relief of Widows and Orphans of Medical Men in London and its vicinity. This is a society which the leading consulting practitioners at the West-end—to their credit be it said—have always given their warmest support. After the death of Sir Charles Mansfield Clarke, Mr. Stone was elected president. He at first declined the proposal, as he was unwilling to follow his uncle immediately in the same office; but he was ultimately pursuaded to accept the post; and no man could more efficiently have filled it, both as regards management and the increase of the capital of the Society. No one within the circle of his acquaintance could fail to know his assiduous exertions in public and in private for the benefit of that society, and in particular for obtaining that charter which now has placed it on the basis of a settled institution. And this was no dignity without work. It is to the credit of the Society that the president and directors pay the closest and most punctual personal attention to the large number of lamentable cases which come before them. As regards his personal tastes and habits, Mr. Stone was of a robust constitution, and fond of shooting, fishing, and active exercise. He had the good fortune to marry, in the year 1823, the eldest daughter of the Rev. Robert Gream, of Rotherfield, in Sussex, a lady distinguished no leess for her personal beauty than for her great piety and charity, who died in the year 1853. By her he had four sons and four daughters—two of the sons clergymen, another in the law, whilst the fourth, who had intended to follow his father's profession, died of cholera in India. Mr. Stone was ill about five weeks, and died, on the 20th inst., at his house in Grosvenor street. His loss will be heavily felt by his professional and private friends and patients, and not less by the members of the large charitable society over which he presided so efficiently for years.—'Med. Times and Gazette.'

MEDICAL NEWS.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF LONDON.—The following are lists of Candidates who passed the respective Examinations indicated:—FIRST B.SC. EXAMINATION.—EXAMINATION FOR HONOURS. *Chemistry and Natural Philosophy. First Class.*—Charles Romley Alder Wright (Exhibition), Owen's; James Campbell Brown, Univ. Aberdeen and S. of Mines. *Third Class.*—William Henry Exall, King's; Charles Graham, University; Albert Kisch, St. Thomas's and London Hospitals. BACHELOR OF MEDICINE. — PRELIMINARY SCIENTIFIC EXAMINATION. PASS EXAMINATION. *First Division.*—*Bushell Anningson, King's College; Frederick Charles Bennett, private study; Edward William Berridge, St. Bartholomew's; William Turberville Buckle, King's College; Joseph Priestnall Cheetham, Guy's; *John Reuben Bathurst Dove, London; Alexander Paull Fiddian, private tuition; William James Garrett, St. Bartholomew's; *William Betts Giles, Guy's; William Richard Gowers, University College; George Arthur Kenyon, St. George's; Albert Kisch, St. Thomas's and London; Thomas Richardson Loy, University College; *Jeremiah McCarthy, M.A. Dub., Dublin University; Francis John Marshall, St. Mary's; Bennett May, Sydenham College, Birmingham; Henry Morris, B.A., Guy's; Henry Franklin Parsons, St. Mary's; George Rolph Raine, Guy's; William Alsept Richards, King's College; *William Benjamin Archibald Scott, University College; *Thomas Claye Shaw, King's College; Frederick Taylor, Guy's; George Alfred Thomas, St. Bartholomew's; William Thomas, Queen's College, Birmingham; Wm. Knight Treves, St. Thomas's; Joseph Williams, St. Thomas's; Charles Romley Alder Wright, Owen's College. *Second Division.*—Edward Homfray Addenbrooke, General Hospital, Birmingham; *John Bonus, [University College; *Herbert Goldingham Budd, Guy's; William Richard Cortis, Guy's; *Stanley Thomas Courtney, St. George's; Edward Bowles Crowfoot, St. Bartholomew's; Walter Greene, Guy's; Frederick Harry Haynes, St. Bartholomew's; *John James, University College; John Wreford Langmore, University College; Richmond Leigh, Liverpool Infirmary; Gysbert Henry Maasdorp, University College; *Duncan McLachlan Maclure, (non-Matr.) Westminster; Henry Flamank Marshall, Sydenham College, Birmingham; Arthur Walter Read, General Hospital, Birmingham; George Rootes, Guy's; Edward Hepburne Seccombe, King's College; Frederick Charles Shaw, St. Bartholomew's; Joseph Wm. Smith, King's College; Herbert Lumley Snow, Queen's College, Birmingham; James Reginald Stocker, Guy's; John Sanderson Wyman, General Hospital, Birmingham.

* Chemistry and Botany only.

EXAMINATION FOR HONOURS.—*Chemistry and Natural Philosophy. First Class.*—Charles Romley Alder Wright, (Exhibition), Owen's College; George Arthur Kenyon, St. George's. *Second Class.*—Henry Franklin Parsons, St. Mary's; Wm. James Garrett, St. Bartholomew's. *Third Class.*—William Knight Treves, St. Thomas's; Albert Kisch, St. Thomas's and London. *Biology. First Class.*—Wm. Richard Gowers (Exhibition), University College; Henry Franklin Parsons, St. Mary's. FIRST M.B. EXAMINATION. PASS EXAMINATION. *First Division.*—Francis Bateman, St. Bartholomew's; Stephen Wootton Bushell, Guy's; Thomas Cole, St. Bartholomew's; Henry Greenway Howse, Guy's; James Pearson Irvine, B.A., University College; Frederick Barham Nunneley, University College; Charles William Philpot, King's College; Thomas Claye Shaw, B.A., King's College; George Christopher Tayler, St. Bartholomew's; John Burges Welch, King's College. *Second Division.*—Arthur Bayley Adams, London; John Augustus Ball, Guy's; Marcus Beck, University College; Charles Berrell, King's College; Other Windsor Berry, Charing cross; Francis John Buckell, University College; Henry Clothier, University College; George Eastes, Guy's; Charles Kelly, King's College; John Lloyd, Queen's College, Birmingham; Charles James Hardy Smith, University College; George Owthwaite Spencer, University College; Arthur Taylor, Guy's; Thos. Pickard Warren, Guy's; John Williams, University College. *Excluding Physiology. First Division.*—John Pearson Hughes, University College. *Second Division.*—Henry Hargreaves Birtwell, St. Thomas's; Julian Augs. Michael Evans, University College; John Spencer Ferris, King's College; Ralph Gooding, B.A., King's College; John Grimes, King's College; John Wickham Legg, University College; George Hunt Orton, St. Bartholomew's. *Physiology only. First Division.*—Thomas Robinson Glynn, St. Bartholomew's; Henry Charles Hilliard, Guy's; John Harward Hooper, St. Thomas's; Arthur George Mickley, Guy's; Ebenezer Fulham Turner, Guy's; Thomas James Woodhouse, St. Thomas's. *Second Division.*—Wm. Hugh Aldersey, Guy's; Walter Anstice Harvey, St. Bartholomew's; Arthur Trehern Norton, St. Mary's; Charles Read, University College. EXAMINATION FOR HONOURS. *Anatomy. First Class.*—James Pearson Irvine (Exhibition and Gold Medal), University College; John Burges Welch, (Gold Medal), King's College. *Second Class.*—Frederick Barham Nunneley, University College; Henry Greenway Howse, Guy's. *Physiology, Histology, and Comparative Anatomy. First Class.*—Henry Greenway Howse (Exhibition and Gold Medal), Guy's; James Pearson Irvine (Gold Medal), University College; George Christo-

pher Tayler, St. Bartholomew's. *Organic Chemistry and Materia Medica and Pharmaceutical Chemistry. First Class.*—Stephen Wootton Bushell (Exhibition and Gold Medal), Guy's; Charles William Philpot (Gold Medal), King's College; Frederick Barham Nunneley, University College; James Pearson Irvine, University College. *Third Class.*—Thomas Claye Shaw, King's College.

BARON LARREY.—The department of the Hautes-Pyrénées has just celebrated the inauguration of the statue erected at Tarbes to the memory of Baron Larrey, Surgeon-in-Chief of the armies of the First Empire. The concourse of people was immense, as every town in the department and all classes of society were anxious to be represented on the occasion. All the local authorities and the principal inhabitants of the town and department assembled at the Hotel-de-Ville to form the *cortège* which was to conduct the present Baron Larrey, son of the illustrious surgeon, to the Cours Napoleon, where the statue had been erected. Dr. Jules Cloquet, of the Institute, especially deputed by the Academy of Medicine; M. Cazalas, Inspector of the Military Medical Service; M. Joly, Professor of the Faculty of Sciences at Toulouse; and M. Juvenal, member of the Legislative Body, walked by the side of the baron. On arriving at the Cours Napoleon the *cortège* was received with loud cheers, and Baron Larrey was at once conducted to the estrade of honour, where he took his seat by the side of Mgr. Laurence, the bishop of the diocese. After the usual formalities, the veil covering the statue was withdrawn, and as soon as the image of Larrey, full of nobleness and animation, became visible to every eye, tremendous cheering burst forth, which was continued for some time. Speeches were then made by M. Garnier, Prefect of the Hautes-Pyrénées; an admirable one by Dr. Jules Cloquet, in the name of the Academy of Medicine; by M. Cazalas, in the name of the Medical Corps of the army; by M. Juvenal, as President of the Academic Society of the Hautes-Pyrénées; and by M. Joly, as representative of the Imperial Academy of Toulouse. All these gentlemen dwelt with great eloquence on the great qualities, genius, patriotism, and eminent services of the great man whose memory they had met to honour, and were most enthusiastically cheered by the multitude. When the ceremony was concluded, the *cortège* was again formed to conduct Baron Larrey to the Hotel de la Paix. The next day a grand dinner was given to Baron Larrey at the Hotel, which was attended by all the principal local authorities, as well as MM. Cloquet, Cazalas, Juvenal, and Joly. The principal toast of the evening, "To the two Larreys, the town of Tarbes!" proposed by the mayor, Viscount de la Garde, was drunk with enthusiasm, and responded to by Baron Larrey in an appropriate speech.

SEA-BATHING.—In the 'Médecine Contemporaine,' Dr. Foubert, the inspector of the baths at Villiers-sur-Mer, advises delicate persons to adopt the following plan to promote reaction after sea-bathing:—The bath should be preceded by a short walk, a flannel wrapper be used before entering and on leaving the water, a hot footbath be ready immediately after the bath, and, if violent shivering should occur, it will be checked by warm fomentations over the thighs and chest. A hot drink will greatly assist in bringing on reaction; dressing must be promptly performed, and active exercise taken if possible in the sun. The best time for bathing is the afternoon or mid-day. But the point which requires most attention is the duration of the bath, which should be in proportion with the amount of vital power of the subject; chlorotic patients should not, especially at first, remain longer than three minutes in the sea. Should these precautions fail in producing reaction, the baths must, for a while, be discontinued, and the strengthening effect of sea-air alone be trusted to. Warm sea-baths may, after an interval, be prescribed at a temperature daily lower, until it is thought safe again to bathe in the sea. In most cases a gradually more rapid reaction will thus be secured, a very essential condition of the utility of sea-baths.—'Journal of Practical Medicine and Surgery.'

WESTERN DISPENSARY, WESTMINSTER: A FEVER NEST.—Dr. Aldis visited a boy ill with fever, at Smith's place, York street, on the 18th inst. The brother, aged twenty, lay dead from typhus fever. On leaving the house, he was entreated by the parents and relatives of other persons struck down with the same complaint to visit them, and before leaving the place he ascertained that there were thirteen cases of fever in nine houses. The patients consisted of children and adults. It appeared that there were two water-butts, one of which had no supply of water, that the inhabitants were entirely without water from Saturday to Monday previously, and that the closets were overflowing before the outbreak of fever.

DISINFECTING PROPERTIES OF MEGASS.—The residue of the sugar-canes which have been crushed in the mill and deprived of their juice is called megass (*bagasse* of French writers). The softer portions are used as fodder, the remainder is burnt. This substance was not hitherto turned to any use, and its antiseptic virtues have been revealed by mere accident. A physician of Georgetown, Dr. W., was commissioned to examine the dead body of a man which had been found concealed in a heap of megass, and to his surprise he remarked that no putrefaction whatever had taken place. He concluded that fresh megass evolves in the process of fomentation a disinfecting gas, which might be applicable to the procedures of public and private hygiene. Before mentioning his discovery, Dr. W. caused several tubs filled with this substance to be placed in a hospital occupied by numerous patients suffering from ulcers and contagious gangrene; the atmosphere of the wards was at once purified, further contagion was checked, and no fresh cases of gangrene occurred. The 'Journal de Chimie Médicale' borrows these particulars from Dr. W.'s communication to the London Society of Arts, and remarks that they confirm the truth of the maxim, "that Nature supplies a corrective for every evil, and that the contagion bred in tropical countries by the heat of the sun will, perhaps, in future be checked by the use of a substance produced under the same warm influence."—'Journal of Practical Medicine and Surgery.'

GERMAN HOSPITAL, DALSTON.—The Duke of Cambridge, the president, has consented to open the new German Hospital on the 15th October next; and the Duchess of Cambridge and the Princess Mary have also graciously promised to honour the festival with their presence. The new structure stands in the centre of what was formerly the hospital garden, in a healthy situation, on a soil composed of gravel and sand. It consists of two blocks united by a corridor. In an architectural point of view it is a handsome and substantial building, and the internal arrangements appear to be all that can be desired.

CHLOROFORM.—A useful and practical debate on anæsthetic aid in midwifery took place in the London Obstetrical Society, at the end of the year 1860, consequent on my reading a few observations on "Obstetric Operations" to the Society.—Dr. Tanner stated that he had never found chloroform do harm, but much good; and it sensibly shortened the after period of convalescence. If he feared hæmorrhage, he gave a large dose of ergot towards the close of the labour, and did not object to the use of chloroform as well. Dr. Barnes doubted the necessity of using chloroform in forceps cases and turning; he had given it in a case of adherent placenta, and witnessed great prostration from it. He had been especially gratified with its use in cases of great nervous excitement, and where convulsions seemed to impend. He believed he had thus averted convulsions, and had certainly accelerated labour. He would like to know what progress chloroform had made in Germany, where interference in labour was so much more general. Dr. Gream had made a full recantation of all his former opinions so opposed to chloroform: he believed there is no city in the world where chloroform is now so much used in midwifery, and amongst the upper classes of society, as in London; still there has not been a single accident in about 40,000 cases. For three reasons he believed chloroform most beneficial in labour: it removed pain, it rendered turning more easy, and it facilitated recovery. The only detrimental effect he had observed was in protracted labour with pelvic contraction, where it seemed to cause delay.

He had seen fewer cases of hæmorrhage also since he had employed chloroform ; indeed, he had exhibited it to patients habitually subject to this occurrence, but without the expected hæmorrhage supervening. He had found inhalers and machines to do mischief ; he preferred a common tumbler and clean pocket-handkerchief. Dr. Druitt gave similar testimony as to the use of chloroform in hæmorrhage cases. In cases of protracted labour from rigidity, such as happen in robust women who marry rather late in life, the blessings of chloroform are incalculable. No amount of torture equalled that which many women endure from excessive uterine action and *quasi* inflammatory rigidity of the os ; and here chloroform agreed well with any other proper remedy (opium and emetic tartar, for instance) ; the only reservation is that chloroform be used in the minutest quantities.—Dr. Kidd, in 'Dublin Quarterly.'

DRINKING FOUNTAINS.—The committee of the Metropolitan Free Drinking Fountains Association have received a contribution of 60*l.* from a lady in Brompton, and of 100*l.* from a gentleman in Pimlico, for the two fountains just opened by the Society outside the Kensington Museum and in the high road leading to Battersea Park. A gentleman in Fifeshire has also offered to pay the cost of a fountain to be erected near the Kensington Potteries, and a lady at St. John's wood has given a donation to the society for the new cattle trough just fixed in Finsbury square. Some liberal contributions to the general fund have also been received during the past few weeks, and the committee are making every effort to erect other fountains before next season. The chairman (Mr. Samuel Gurney) states that 87 fountains, 3 cattle troughs, and more than 50 dog troughs have now been opened by the society, but that, notwithstanding this success, whole districts remain as yet without a single fountain, and 400 more would not fully supply the need of the metropolis.

DEATH FROM HYDROPHOBIA.—A death resulting from this dreadful malady has occurred in Bandon. It appears that about six months ago a fine powerful young man named Joseph Horsford, a servant in the employment of the Earl of Bandon, was endeavouring to administer a dose of castor-oil to a huge mastiff, who was kept in the stable-yard at Castle Bernard. While so engaged, with his thumb in the animal's mouth, the dog made a sudden snap, and drove two of his teeth with such force into the upper joint of the thumb that they penetrated almost through the bone and produced a tedious wound, which it took several weeks to heal. As the dog, who was merely suffering from an attack of worms, betrayed no trace of madness, the affair was soon forgotten, and no one thought anything more about the matter until Thursday last, when poor Horsford for the first time betrayed unmistakable symptoms of hydrophobia. When he was given a piece of bread soaked in water he was seized with spasms, and spat it out violently ; and when he was shown a looking-glass the poor fellow mistook it for water, and immediately the frothing at the mouth became profuse, and his contortions terrible. Upon the appearance of the first indication of this dire disease the noble family in whose employment he was called in some of the first medical men in Bandon, and telegraphed to Cork for additional medical assistance ; but all was in vain. An attempt was made to place him under the influence of chloroform, but without success. Every effort which kindness could devise or medical skill could accomplish was tried, but without producing any apparent benefit. The unfortunate man suffered intensely, and gradually kept sinking until he died, which was on the second day after the first symptoms became apparent.—'Cork Examiner.'

BEQUESTS.—The late Mr. Thomas Robinson, of Sandford House, Bootle, near Liverpool, has bequeathed the munificent sum of nearly 10,000*l.* to the local charities : amongst them, to the Royal Infirmary, 1,000*l.* ; the Northern Dispensary, 600*l.* ; the Southern Dispensary, 600*l.* ; the Northern Hospital, 500*l.* ; the Southern Hospital, 500*l.*—The late Mr. Martin Thackeray has bequeathed 500*l.* to the Bedford Hospital.

MORTALITY OF THE CITY OF LONDON DURING THE LAST QUARTER.—Of the deaths in the City of London during the last quarter, about 41 per cent. have been among children of less than five years of age ; 33 per cent. of persons from twenty to sixty years of age ; and 19 per cent. of persons aged sixty and upwards. The total amount of sickness amongst the poor has been less than usual.

APPOINTMENTS FOR THE WEEK.

WEDNESDAY, AUGUST 31.—*Operations* at Middlesex Hospital, 1 p.m. ; St. Mary's Hospital, 1 p.m. ; St. Bartholomew's Hospital, 1½ p.m. ; Great Northern Hospital, Caledonian road, 2 p.m. ; University College Hospital, 2 p.m. ; London Hospital, 2 p.m.

THURSDAY, SEPT. 1.—*Operations* at St. George's Hospital, 1 p.m. ; Central London Ophthalmic Hospital, 1 p.m. ; London Surgical Home, 2 p.m ; West London Hospital, 2 p.m. ; Royal Orthopædic Hospital, 2 p.m.

FRIDAY, SEPT. 2.—*Operations* at Westminster Ophthalmic Hospital, 1½ p.m.

SATURDAY, SEPT. 3.—*Operations* at St. Thomas's Hospital, 1 p.m. ; Lock Hospital, Dean street, Soho, Clinical Demonstrations and Operations, 1 p.m. ; St. Bartholomew's Hospital, 1½ p.m. ; King's College Hospital, 1½ p.m. ; Royal Free Hospital, 1½ p.m. ; Charing-cross Hospital, 2 p.m.

MONDAY, SEPT. 5.—*Operations* at St. Mark's Hospital for Fistula and other Diseases of the Rectum, 1½ p.m. ; Metropolitan Free Hospital, 2 p.m.

TUESDAY, SEPT. 6.—*Operations* at Guy's Hospital, 1½ p.m. ; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

*** It is requested that all Communications intended for the Editor may be sent to the office of the Journal, No. 20 King William street, Strand.

In order to obviate the recurrence of disappointments, we beg to state that all communications intended for this Journal should be sent to the Office *before noon* on Monday, as we are compelled to go to press on the afternoon of that day.

TO SUBSCRIBERS.—Gentlemen who receive the MEDICAL CIRCULAR direct from the Office, and who have not paid their subscriptions, are respectfully reminded of the omission.

Post-office orders should be made payable to Mr. Thomas Rolfe, at the Charing-cross Post office.

MR. T. HARRISON MARSHALL'S letter is inserted.

DR. R. M.—Some doubt has been expressed as to the Calabar bean having really been the poison which was eaten by the children at Liverpool. The bean has been so scarce that it could with difficulty be procured for medical purposes ; and as its use in commerce is unknown, it was not very intellit gible that a shipload of the seeds should be discharged a one of our ports. But we believe that all doubt on the sub ject is at an end, for the beans are now in Liverpool in great quantities, although the questions how and why they came there is not yet determined.

ANTHROPOS.—We do not admire such sharp practice, but the parties concerned must fight it out for themselves.

DR. KIDD'S letter is inserted.

A GEOLOGIST.—The question of the antiquity of man is not to be determined by such shallow reasonings as those referred to. Although human bones have not been discovered in the Brixham Cave, yet a flint instrument, evidently of human manufacture, has been found in conjunction with the bones of extinct mammalia, as the cave-bear, the mammoth, and others.

DR. S. B.—The letter has been received.

AN ASPIRANT.—There is not much difference as to the rewards offered for Natural Science at Oxford and Cambridge, but both the Universities are making efforts to encourage those studies.

A DEVONSHIRE PHYSICIAN inquires where he can obtain skim milk in that county at the rate of twelve pints for threepence, as stated by the 'Times' on the authority of Dr. E. Smith.

J. H. PARK.—The communication has been received.

THE letter of our Dublin Correspondent is unavoidably postponed until next week.

Prizes in Materia Medica and

PHARMACEUTICAL CHEMISTRY.

The Examination for the Society of Apothecaries' Annual Prizes in Materia Medica and Pharmaceutical Chemistry will be held at the Hall of the Society, on Wednesday, the 19th, and Friday, the 21st of October, at 10 a.m. to 1 p.m., viz.—Wednesday for Writing, and Friday for Vivâ voce.

The Prizes consist of a Gold Medal and a Silver Medal with a Book.

Gentlemen being Medical Students will be eligible as Candidates for such Prizes who shall have commenced the third Winter Session of their Medical Study.

Candidates must send a written notice to the Office of the Beadle of their intention of competing for the Prizes on or before the 7th day of October.

By order of the Court of Assistants,
R. B. UPTON, Clerk to the Society.

Apothecaries' Hall, August, 1864.

St. Bartholomew's Hospital and

MEDICAL COLLEGE.—The WINTER SESSION will commence Oct. 3, with an Introductory Address by Mr. CALLENDER, at 5 o'clock p.m.

LECTURERS.

Medicine—Dr. Black and Dr. Kirkes.
Surgery—Mr. Lawrence and Mr. Coote.
Descriptive Anatomy—Mr. Skey and Mr. Holden.
Physiology and General Anatomy—Mr. Savory.
Chemistry—Dr. Odling.
Demonstrators of Anatomy—Mr. Callender and Mr. Smith.
Demonstrators of Morbid Anatomy—Dr. Andrew.

SUMMER SESSION, commencing May 1, 1865.

Materia Medica—Dr. Farre.
Botany—Dr. Harris.
Forensic Medicine—Dr. Martin.
Midwifery—Dr. Greenhalgh.
Comparative Anatomy—Mr. Callender.
Practical Chemistry—Dr. Odling.

The Hospital contains 650 beds, and Clinical Lectures are delivered—On the Medical Cases, by Dr. Farre, Dr. Black, and Dr. Kirkes; on the Surgical Cases, by Mr. Lawrence, Mr. Paget, and Mr. Coote; and on Diseases of Women, by Dr. Greenhalgh.

Collegiate Establishment.—Students can reside within the Hospital walls, subject to the collegiate regulations. Some of the teachers connected with the Hospital also receive Students to reside with them.

Seven Scholarships, varying in value from 20*l.* to 50*l.*, are awarded annually. Further information respecting these and other details may be obtained from Dr. Edwards, Mr. Callender, or any of the Medical or Surgical Officers or Lecturers; or at the Anatomical Museum or Library.

Anatomy, Physiology, Pathology,

and SURGERY.—Mr. TUSON, formerly Surgeon to the Middlesex Hospital, continues his Instructions and Examinations daily at his residence, 6 Devonshire street, Portland place. These Instructions are illustrated by Anatomical Preparations, recent Dissections, and Models. Each course, Five Guineas.

6 Devonshire street, Portland place.

A vacancy for a Resident PUPIL.

Mr. Howard, Surgeon Dentist,

52 FLEET STREET,

has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble natural teeth as not to be distinguished from the original by the closest observer, they will never CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does NOT REQUIRE the EXTRACTION of ROOTS, or any PAINFUL OPERATION, and will support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication. Decayed teeth stopped, and rendered sound and useful in mastication.—52 FLEET STREET. At home from Ten till Five.

Pepsine and Pepsine Wine.—Boul-

DAULT begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Chemist in Ordinary to the Queen and H.R.H. the Prince of Wales, 227 Oxford street, London, to whom all applications respecting it must be addressed.

Third Edition, with Further Remarks by Dr. CORVISART, Physician to the Emperor of the French, edited by W. S. SQUIRE, Ph. D.: published by J. Churchill, London; may be also had of the Author, 277 Oxford street, price Sixpence.

Quinine.—The Medical Profession

—the LANCET—Dr. Hassall, and others, recommend "Waters' Quinine Wine" as an excellent and simple stimulant. Manufactured only by ROBERT WATERS, 2 Martin's lane, Cannon street, London, E.C. Sold by Grocers, Italian Warehousemen, and others, at 30s. a dozen.

Wholesale Agents, E. Lewis & Co., Worcester.

TO THE MEDICAL PROFESSION.

Bragg's Charcoal Biscuits for

INDIGESTION, HEARTBURN, &c. &c., manufactured from the purest Vegetable Carbon. Sold only in tins, at 1s., 2s., 4s., and 8s. each, by J. L. BRAGG, Sole Manufacturer, 2 Wigmore street, Cavendish square, London. Also "IRON TONIC BISCUITS," in 2s., 4s., and 8s. Tins.

Chemists and others allowed a liberal discount.

Post office Orders made payable at the Old Cavendish-street Branch.

A Cup of Coffee in One Minute.

—DUNN'S ESSENCE of COFFEE, 1s. and 2s. pe bottle. May be had everywhere. Warranted to keep good in any climate.

Struve's Seltzer, Fachingen, Vichy,

MARIENBAD, and other MINERAL WATERS. Under Her Majesty's especial patronage. ROYAL GERMAN SPA, BRIGHTON. STRUVE'S Pump-Room, offering every facility for a course of Mineral Waters as perfect and beneficial as the natural springs, is now open for the Fortieth Season, and will close in November. A Prospectus, with the highest medical testimonials, may be obtained gratis at the Pump-Room, and from GEORGE WAUGH and CO., Pharmaceutical Chemists to the Queen, 177 Regent street (west side), London, and numerous other respectable houses in London and the provincial towns, where orders for Struve's Bottled Waters continue to be executed.

CAUTION.—The success obtained by Struve's Mineral Waters, owing to their perfect identity with those of the natural springs, has induced several parties to attempt imitations, sold as "BRIGHTON Seltzer," "BRIGHTON Vichy," &c., an analysis of some of which has shown an utter disregard of their true chemical composition.

To distinguish STRUVE'S Waters from all others, every bottle has a label and red ink stamp over the cork, each bearing Struve's name, without which none is genuine, even though contained in STRUVE'S bottles.

New American Preparations.—

W. TWINBERROW begs to inform the Medical Profession that he has had a large consignment (direct from Keith & Co., of New York) of ALL the MOST VALUABLE American Medicinal Preparations. Also—

EXT. CANAB. INDICA, direct from Calcutta.
PIERLLOT'S VALERIANATE of AMMONIA.
Manufacturer of the New Preparation of
PEPSINE with Wine—PEPSINA PORCI—Ditto VITULI.
PHARMACEUTICAL CHEMIST.

Edwards street, Portman square, and 59B Westbourne grove, London.

Jozeau's Copahine Mege.—Copaiba

and Cubebs are doubtless the best remedies, but are of a repulsive taste and odour, and occasion colicky pains, nausea, and gastric disturbance. M. Jozeau has succeeded in rendering them perfectly innocuous by increasing all their curative properties. It has been adopted by the Paris Academy of Medicine after more than a thousand trials in Paris and the different London hospitals, viz., St. Thomas's, Guy's, and St. Bartholomew's, under the care of Messrs. Lloyd, Poland, and Legros Clark. —'Lancet,' Nov. 6, 1857. The Copahine, which is in form of a pretty pink sugar plum, effects a cure in about six days. 100 Capsules, 4s. 6d.; post-free, 5s. 2d. — At G. JOZEAU'S, French Chemist, 49 Haymarket, London; 22 Rue St. Quentin, Paris; and all Chemists.

Hedges & Butler, Wine Merchants,

&c., recommend and GUARANTEE the following WINES:

Pure Wholesome CLARET as drank at Bordeaux, 18s. and 24s. per dozen.

White Bordeaux	24s.	and 30s.	per dozen.
Good Hock	30s.	,, 36s.	,,
Sparkling Epernay Champagne, 36s.,	42s.	,, 48s.	,,
Good Dinner Sherry	24s.	,, 30s.	,,
Port	24s.,	30s. ,, 36s.	,,

They invite the attention of CONNOISSEURS to their varied Stock of CHOICE OLD PORT, consisting of Wines of the

Celebrated Vintage 1820	at 120s.	per dozen.
Vintage 1834	,, 108s.	,,
Vintage 1840	,, 84s.	,,
Vintage 1847	,, 72s.	,,

All of Sandeman's shipping, and in first-rate condition.

Fine old "beeswing" Port, 48s. and 60s. superior Sherry, 36s., 42s. 48s.; Clarets of choice growths; 36s., 42s., 48s., 60s., 72s., 84s.; Hochheimer, Marcobrunner, Rudesheimer, Steinberg, Liebiraumilch, 60s.; Johannesberger and Steinberger, 72s., 84s., to 120s.; Brauneberger, Grunhausen, and Scharzberg, 48s. to 84s.; sparkling Moselle, 48s., 60s., 66s., 78s.; very choice Champagne, 66s., 78s.; fine old Sack, Malmsey, Frontignac, Vermuth, Constantia, Lachrymæ Christi, Imperial Tokay, and other rare wines. Fine old Pale Cognac Brandy, 60s. and 72s. per dozen; very choice Cognac, vintage 1805 (which gained the first-class gold medal at the Paris Exhibition of 1855), 144s. per dozen. Foreign Liqueurs of every description. On receipt of a post-office order, or reference, any quantity will be forwarded immediately by

HEDGES & BUTLER,
London, 155 Regent street, W.; and 30 King's road, Brighton
(ORIGINALLY ESTABLISHED 1667.)

Fine Old Port, Twelve Years in

Wood, 42s. per dozen. Dinner Sherries, 24s., 28s., 32s. Clarets, 14s., 18s., 24s. per dozen.

Bass's Ale, Scotch Ale, and Guiness's Stout, 6s. Quarts; 3s. 6d. Pints; 4s. 6d. Imperial Pints. Light Pale Ale for Summer use, 4s. 6d. Quarts 2s. 9d. Pints; 3s. 6d. Imperial Pints, per dozen.

WOOD and WATSON, 16 Clement's lane, E.C.

Kinahan's LL Whisky v. Cognac

BRANDY.

This celebrated Old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, and very wholesome. Sold in bottles, 3s. 8d. each, at most of the respectable retail houses in London; by the appointed agents in the principal towns in England; or, wholesale, at 8 Great Windmill street, Haymarket.—Observe the Red seal, pink label, and cork branded "Kinahan's LL Whisky."

Flour — (Essex) — Warranted free

from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs.), 9s. 0d. Households (recommended for bread-making), 7s. 8d.; Seconds, 7s. 0d.; Wheat Meal for brown bread, 7s. 0d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 355 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any railway station 200 miles. German yeast.

The Medical Circular.

ORIGINAL COMMUNICATIONS.

ORIGIN AND NATURE OF SYPHILIS.

By RICHARD SAMUEL SISSON, M.D.

(Continued from page 137.)

The following case of vaccination, reported by Mr. R. O. Clark, at that time Resident House-Surgeon to the Royal South Hants Infirmary, in the 'Med. Gaz.', 1850, vol. xi., N.S., seems to bear so closely on the present subject that I make no apology for quoting it *in extenso*:—

"On the 28th of August last," says that gentleman, "I was requested to vaccinate John Hillesden, æt. nine months, a fine healthy child, who, his mother told me, had scarcely had an hour's illness since his birth—a case promising well that the vaccine should take due effect. I inquired very particularly into the present state of the secretions, &c., and found all in proper order. The breast had been as yet the only source from which his nourishment had been derived. Three good incisions were made with the lancet in the upper part of the left arm over the belly of the deltoid muscle, and I inserted into each successively two points well charged with the matter which had been sent me by the National Vaccine Establishment. Not more than the usual bleeding occurred during the operation, and not the *slightest abrasion of the cuticle could be seen on any other part of the arm, nor was any scratch made during vaccination.*

"On the 30th there seemed a slight disposition to the formation of vesicles; but during the next day all redness disappeared, nor did any further signs of the matter having taken effect show themselves at this spot. On the evening of Sept. 2nd the mother noticed what she considered a small red pimple *about the middle of the forearm*, and on my visiting the case next morning she showed it to me. It was then larger, and had, in my opinion, all the characters of a cow-pox vesicle, of about the third day after vaccination.

"I watched the case daily, and became more and more convinced that it was genuine cow-pox. Still, not liking to rely on my own judgment in so unusual a case, on the 6th Sept. I showed it to my father, and his opinion entirely coincided with mine. It subsequently ran through all the successive stages of a common cow-pox vesicle; and had I not known in what part of the arm the child had been vaccinated, and that the cuticle of the forearm was previously quite sound, I should have unhesitatingly said the matter was inserted at this spot, and that all was going on in a normal way. As, however, I had never seen an exactly similar case before, I confess I was inclined to be rather sceptical on the point, in spite of my convictions to the contrary. I therefore determined to vaccinate the child in the other arm on the fourteenth day after the primary vaccination, and obtained a fresh supply for that purpose from the National Vaccine Establishment. I inserted into four incisions a quantity of matter from glasses, and subsequently four points well charged with the lymph. No other effect was produced than would have followed a simple scratch—viz., there was a little redness of the part for a couple of days. Feeling sure the case was a curious one, I wrote to Dr. Gregory, of the Small-pox Hospital—one of the greatest authorities of the day, I presume, on these matters. He seemed even more sceptical on the case than I had been, and told me,' if the single vesicle were *bonâ-fide* cow-pox, the case was a very curious one indeed—undoubtedly the first of the kind that ever happened,' and that 'some still stronger testimony would be desirable to prove it such. This testimony would be supplied only by the insertion of *very efficient fluid lymph* into the arm of the same child. If under such renewed application of an active virus (performed so as to leave no shadow of doubt that the second vaccination had been decidedly performed) the child should remain unaffected, we must believe the constitutional vesicle you saw on the forearm was "*genuine vaccinia*;" but, on the contrary, if the second vaccination rises into good vesicles, it is clear that the first vesicle was only ecthyma.' He advised my giving the child two alterative doses of calomel before again vaccinating him, and offered to charge two lancets for me with '*matter of undoubtedly good character.*' I sent him two fine and sharp, which he charged from two different children; and the boy was, on Sept. 26th, revaccinated with this lymph, about nineteen or twenty hours after it was taken. This, the Doctor considered, would put the case beyond doubt; but he anticipated that the revaccination would take effect, and that the first vesicle would then be proved to be ecthyma.

"However, no such result followed; the vaccination was done efficiently, and the only effect produced was just that which occurred after the first revaccination and nothing more, not the least inclination ever showing itself for a vesicle to rise. No constitutional disturbance whatever was present."

As Mr. Clark's experiments were evidently conducted for the sake of eliciting truth, and not merely with the view of supporting a new theory, the case must be considered as all-sufficient to prove that an animal poison may be absorbed into the economy, and produce constitutional effects, without the necessary intervention of a local disease at that point where the poison gains entrance.

If the natural secretion from the genital organs of an individual tainted with syphilis can communicate the disease to another, then I think it must be conceded that the same results will ensue from the gonorrhœal discharge, the seminal fluid, and the vaccine lymph of a person similarly circumstanced.

Dr. Price, of Margate, has published a case in the 'Lancet,' 1846, by which it is shown that the milk of a secondarily infected nurse will communicate the disease to her nurse-child; and such cases are, I believe, not uncommon. It is curious, however, to note with what pertinacity some writers combat such facts; and though it is a matter of daily occurrence for the wives of men constitutionally affected to escape contamination until pregnancy occurs, or for the ovum to be tainted, and the woman escape altogether, we find Siegmund making this statement:—"The transmission of syphilis from parents to children is direct as regards the mother, and indirect as regards the father. A transmission of it by the semen has not yet been proved."—('Med. Times and Gaz.', 1861.)

And Dr. Charrier endeavours to show that a child affected with hereditary syphilis must have a mother who is, or has been, syphilitic, and that the father has no direct influence in producing the disease.—('New Syd. Society Year-Book, 1862.')

For the sake of the women of the present generation, and of the children of that which is to come; for the sake of man's own peace of mind, and as some restraint upon the reckless, I hope the day is far distant when such a doubtful and, I believe, erroneous doctrine shall be circulated amongst us. The result of such an event would be an amount of misery and degradation awful to contemplate, and already, alas! too widely spread, even under existing circumstances.

The following is an extract from the 'New Syd. Society Year-Book, 1859':—

Apropos of two cases in which syphilis followed immediately on, or rather was blended with, variola, Bamberger makes the following remarks:—"The interest of these cases consists not so much in the circumstance of syphilitic subjects being attacked by variola, but rather in this, that under the eye of the observer the specific variolous pustule passes into the equally specific product of constitutional syphilis, the change taking place in such a manner that it cannot be determined when the efflorescence ceases to be the one and begins to be the other. It is impossible not to assume that the individual efflorescence, as soon as it is placed under the influence of the two forms of disease holding sway over the system, contains also in itself the pro-

duct of both." The editor remarks:—"According to this, it seems undeniable that if a healthy child were inoculated with vaccine matter from another labouring under constitutional syphilis, the latter disease might also be communicated as well as the vaccine infection."

Can the Syphilitic Virus be eradicated by Time or Treatment?

The honourable medical man can, I think, feel no greater responsibility devolving upon himself than when called upon to answer the question, Is it safe for a man to marry who has been affected with constitutional syphilis?

It has been argued that the infecting chancre can be contracted but once, and thence it has been inferred that the syphilitic remains syphilitic for life. Now, it is evident that, even were the premise true, the conclusion may be false. Would it not be equally philosophical to conclude that because a second vaccination or a second inoculation for small-pox proved abortive, therefore those poisons still remained active and uneliminated?

That a certain diathesis is created by the absorption into the system of the syphilitic virus is a reasonable inference from what occurs in other diseases of like nature; and that this virus will be in time eliminated as the viri of those diseases are, is an equally reasonable inference.

Hospital patients are not the best upon whom to study the natural course of this disease. Their irregular mode of life, their intemperate, immoral, and filthy habits nullify remedies, thwart Nature, and render them continually liable to contract fresh disease, for which they seek fresh advice, and so on, until at last, coming again under the hands of their old doctor, they deny all their intermediate ailments. Their surveillance whilst in hospital is evidently insufficient in point of time to be of any value in deciding this question, for it must be admitted that syphilis adheres long and pertinaciously to the constitution.

That the syphilitic poison, however, can be eradicated, and occasionally in a short time, is evident from the following case recorded by Mr. Lee in the 'Lancet,' 1862:—"A gentlemen had a syphilitic sore, which was followed by a general eruption on the skin. He then passed two years in the West Indies. After this he returned home with the faint brown stains of the eruption still visible. In London he contracted fresh disease. Two well-formed indurated and circular chancres presented themselves on the glans penis. In a few weeks these were followed by a well-marked crop of syphilitic lepra, of a bright copper colour, and quite distinct in appearance from the brown stains of the first eruption."

Mr. Acton expresses his opinion thus:—"I think it neccssary somewhat to qualify this strong statement (Ricord's) of the incurability or ineradicability of the syphilitic diathesis. Obstinately as it adheres to the constitution, I believe from experience, as well as analogy, that it will wear out."

M. Diday has published an elaborate paper on second attacks of syphilis; and he remarks: "Although these facts appear new, they would long since have been well known had not practitioners allowed themselves to be blinded by doctrines which, though true in most, are not absolutely so in all cases." To this statement of Diday's I most fully subscribe, believing that had this not been the case so many false dogmas respecting syphilis could never have been so widely disseminated. Diday in his own practice, in six years, met with twenty examples of reinfection, which he says proves that syphilis may be radically cured—a fact denied by many authors. The mean minimum time is twenty-two months.—('New Syd. Society Year-Book, 1862.')

Perhaps the views I have been advocating with respect to this most complex subject may be rendered clearer by the following recapitulation:—

Since man is organised as he ever was, and has for ages been subjected to the same influences as now, so syphilis has ever existed, or at all events since those influences were in operation.

Since most zymotic diseases are now proved to arise spontaneously, and since syphilis must have first arisen in that way, so may it arise now.

The unity of the syphilitic virus is admitted, and the unity of the chancrous virus seems all but proved.

Induration of a chancre is a sign of constitutional infection, which may take place at any time, or not at all.

No one can pretend to limit in either direction the precise number of points which must be attacked in any syphilitic outbreak; therefore Ricord's dogma is not true that indurated chancre is invariably followed by (other) constitutional symptoms.

It is reasonable to suppose that the syphilitic virus may be absorbed and produce constitutional effects without the necessary intervention of a local sore.

The first result of such absorption *may be* bubo.

The character of a bubo, like all the manifestations of syphilis, is determined by the constitutional peculiarities of the individual.

Any of the secretions, morbid or natural, of a contaminated individual may act as a focus of contagion to a healthy person.

Tertiaries so-called are the results of a cachexia produced by the syphilitic virus, and are not different from the results of cachexiæ which arise from other causes.

The evolution of syphilis is irregular in all its phases.

The syphilitic virus may be eradicated, and the diathesis produced may be overcome.

CASE OF PARTIAL RUPTURE OF THE UTERUS.

By J. H. PARK, M.D.

On the 4th of July, 1863, I was called in to Mrs. B., in labour with her first child, the midwife being in attendance, but the friends getting impatient. On examination, I found the head presenting—first position; the os about the size of a florin; pains moderate and continuous. The woman was young and strong, but most impatient; and the midwife directed my attention to the peculiar shape of the abdomen, which was greatly protuberant superiorly—in fact, reversing the shape of the abdomen usually found in labour. With the assistance of moderate dilatation with the finger, the os fully opened and the head descended, and then remained impacted for an hour at the floor of the pelvis, notwithstanding continuance of the pains. I then applied the forceps, and having got the head born succeeded, with great difficulty, in extracting the rest of the body, the uterus apparently giving little or no aid. The abdomen still preserved its original strange appearance, and on introducing the hand the whole of the placenta was found firmly adherent to the fundus, this condition being probably caused by several kicks on the abdomen which (I then learned) the poor woman had received during her pregnancy.

For upwards of an hour my continued efforts to separate the placental mass were unavailing, not a single portion of it being detached. As my hand was getting quite cramped, I called in the assistance of another practitioner, before whose arrival, however, I succeeded in getting it away.

There was not much flooding, but the woman was considerably exhausted. On again introducing my hand to get the womb to contract properly (there being hour-glass contraction), I was mortified to find what I considered still a piece of placenta hanging from the lower and back part of the uterus. I passed my fingers round it but used no force, as at its upper part it was quite continuous with uterine substance. We both were at a loss to account for it, and thought it prudent to call in the assistance of a practitioner of much greater experience than either of us. The placenta was carefully examined, and, though torn, was found to resemble the entire mass. We then each examined the uterus and succeeded in satisfying ourselves that what we felt hanging down was in reality a portion of the mucous and muscular walls of the uterus itself. The tear was from below upwards, and of a semi-circular shape, and must have involved one-half of the thickness of the posterior wall. It felt very like the placenta, without the lobulated feel of the latter. There can be little doubt that, in the weakened state of the uterus, arising from the inflammation required to produce such extensive placental ad-

hesion, the tear was the result of the violent contraction of the organ itself. Had the direction of the rent been reversed, it would have been a question whether I had not produced it by my efforts at abstraction. The woman was so much exhausted and depressed that a fatal issue was looked for; but, by a liberal use of stimulants and opium, she made an excellent recovery.

The result was not only gratifying to her medical attendants, but must have afforded considerable satisfaction to the husband.

Broughty Ferry.

HOSPITAL REPORTS.

By Dr. G. de Gorrequer Griffith.

KING'S COLLEGE.

Operations by Mr. Henry Smith.

Case I.—A little boy, aged about five years, of apparently good health, and with a clear, florid complexion, of a thin, spare habit, yet not at all of a delicate appearance, was suffering from disease of the knee-joint. He was placed under the influence of chloroform, and the condition of the articulation was then more minutely examined by Mr. Smith.

As the child lay on its back, the limb was seen to be flexed upon itself, almost, if not altogether, at right angles; the joint was considerably enlarged and looked even greater than it really was, owing to the emaciation and wasting which had taken place in the thigh above it and in the calf of the leg below: there was, leading down to the bone and into the interior of the joint, a number of sinuses; and on the inner aspect of the joint was a large red surface, where the integument had become stripped off, and the surface lying immediately beneath had become altered. This red, unhealthy-looking sore was pathognomonic of the nature of the diseased action.

Grasping the knee with the left hand, and steadying the entire limb—which was likewise supported at the foot and a little above it by an assistant—while compression was exercised by Mr. Mason upon the artery, as it lies close to the ilio-pectineal eminence, Mr. Smith entered the knife a little above the articulation and directly in front of the lowermost third of the femur. The instrument was then made to cut its way out and to form the anterior flap; afterwards it was entered posteriorly behind the bone, and as it was being withdrawn the posterior flap was formed.

The operation was performed with the utmost possible celerity, and scarcely any blood was lost, even though a large number of vessels had to be tied. The flaps, brought together with a sufficiency of *thread* sutures, were then supported by strips of adhesive plaster, over which were then placed strips of wetted lint, so as to give further support, and all were then enveloped in the folds of a calico bandage.

The child woke up very quickly from the influence of the chloroform; and here we would note that we have often remarked the same to take place in children of tender years and in *young* persons of yet more mature years, but who are considerably under middle age, and the more especially so if the chloroform be very good and pure.

Mr. Smith, in the remarks which he made subsequent to the operation, dwelt upon the fact that such a measure as he had just carried out in the case of this patient was now of very infrequent occurrence since preservative surgery had become the fashion and had worked so complete a change in the minds of surgeons.

Before beginning the operation it was the intention to amputate through the joint; but, as there was very great disorganisation of the articular extremities of the bones, this plan was abandoned in favour of amputation immediately above the joint.

The lower third of the femur, for a distance of some inches, was completely stripped, not alone of the soft fleshy tissues by which it ought to have been covered, but likewise of the periosteum; this denudation was particularly marked on the anterior and outer surfaces of the bone to which the sinuses led down. The posterior surface of the tibia was also laid bare and had a large sinus communicating with it, through which the probe was passed down to the bone, which was then ascertained to be dry and altogether dead. In addition to this condition of the tibia, the lower end of the femur was actively engaged in the same morbid process as had destroyed the bone of the leg.

Case II.—Amputation through the knee-joint was intended, but, owing to extensive disease of the parts, amputation above the articulation was performed. The patient was an elderly woman, of intemperate habits, and some time previously had received an injury which had caused a compound fracture at the knee-joint of the left lower extremity. The fracture was supposed to have extended itself into the neighbouring articulation, and the supposition was strengthened by the distinct and very peculiar grating heard and felt as the leg and thigh were moved on each other. After the fracture there had supervened extensive disease of the joint, and the patient had fallen into bad health; on her admission she was very low, not only from the disease, but also from her dissipated habits, and required every kind of nourishment as well as an abundant supply of stimuli to raise her from her depression and keep her from again sinking below par.

The woman presented an appearance as though she had formerly enjoyed robust and excellent health; she, however, now wore an anxious and careworn expression, but notwithstanding the gravity of the affection under which she laboured was not very much emaciated.

Every endeavour had been made to save the limb before resort was made to amputation, which was undertaken, altogether, as an ulterior measure, nor until every effort to effect a healthy change had been unsuccessful.

The leg, which on moving caused exquisite pain to the patient, had been placed by Mr. Smith on a straight splint that ran upwards above the knee and terminated below in a foot-piece, against which the foot rested; the splint was well padded and had sides to it, which, though not reaching far forwards upon the leg, yet gave steady and effectual support to the entire member. Instead of the ordinary calico roller, a flannel bandage was used, as communicating more warmth and comfort to the patient.

When the patient had been brought under the full influence of chloroform, Mr. Smith made an incision down upon the patella, in such a manner that the edge of the knife should correspond to the medial transverse line of that bone, and then dissected up the integuments with a view to getting into the joint and performing that operation which is usually termed amputating through the joint. In making his incisions and opening into the articulation, so much disorganisation had taken place, that Mr. Smith deemed it advisable to alter his original intention, and to remove the entire joint with all the parts below it—to perform, in fact, amputation at the lower third of the femur but as close to the joint as the disease would allow.

In accordance with the alteration of intention, there was, of course, a necessity for alteration in the procedures; but such was the nicety of manipulation, and the skilful tact called to bear upon it, that the change in manner could hardly be noticed or appreciated by the lookers-on, a great number of whom, even after the completion of the entire operation, were not aware of any alteration.

The joint was opened into from the front, and presented an immense amount of disease. The cartilages were *completely* removed from the joint. Mr. Smith stated that he had never seen an instance of such complete removal; those covering the tibia as well as those which terminated the femur, and those lining the internal surface of the patella, were all eroded. There was, however, no evidence of fracture either of the tibia or of the femur. An immense quantity of pus flowed from the inner side of the femur as soon as the soft parts had been sufficiently opened to allow of its escape.

The posterior flap was taken from the soft parts covering the lowermost part of the back of the thigh as well as from those composing the calf of the leg, and by many was supposed to be of too great a length to form a nice pad or support upon which the body could subsequently rest; but

Mr. Smith took opportunity to call attention to the facts that the skin would shrink, the muscles waste away or become converted into fibrous tissue, and that all the parts would be so altered after the lapse of some little time, that unless the flap were left long enough the bone might protrude; or, if such did not occur, that at least a comparatively useless stump might be given to the patient, as the skin would be too tightly stretched across the end of the bone, and the remaining part of the limb would be rendered cumbersome rather than otherwise, as it could hardly be used either from the pain that would be occasioned on pressure, or from the danger of ulceration at the point of pressure.

In the obstetric ward we saw a very interesting case, under the care of Dr. Playfair.

The patient was a woman aged about thirty, who had borne a few children and had miscarried upon different occasions. She was pale and anæmic, the face and surface of the body being completely blanched; the eyes were sunken and glassy, and were circumscribed by a dark halo; the forehead was white and had the skin stretched tightly upon it; the cheeks were hollowed; the nose pinched; the lips paled but not yet bloodless; and the entire countenance wore a melancholy and cadaverous appearance. The tongue was red, though not harsh and dry; the pulse was quick, easily checked by compression, small, and frequent. The surface of the body was cool and bedewed with moisture; the abdomen was evidently distended beyond its natural dimensions; but on the occasion of our visit we could not make any manual examination, as the pain felt on pressure—no matter how lightly laid on—was too excessive.

Dr. Playfair, however, mapped out the abdominal tumour and showed how far it extended itself laterally as well as in an upward direction, and also pointed out the position of the fœtal prominences. The entire tumour was very distinctly marked, and its boundary lines were ascertainable without any difficulty. It did not reach higher than about midway between the umbilicus and the ensiform cartilage, and in its lateral dimensions it did not altogether engage that region of the abdomen which lies between the ossa ilii. There had at no time been any discharge of purulent matter from either the vagina or the rectum, nor at any time had fœtal remains escaped by either of these outlets.

The history pointed, perhaps, more to rupture of the uterus and extrusion of the fœtus into the abdominal cavity than to extra-uterine fœtation. The woman had conceived; had gone to a certain time in her pregnancy without experiencing any unusual or untoward sign or symptom. When on one occasion she felt a sudden pain in the inside of the abdomen, and which she described as followed by some not very considerable constitutional disturbance, by a sense of faintness and nausea, the latter being followed by actual emesis. At no time had the patient voided from the bladder either pure pus or urine mixed with purulent matter.

The os and cervix uteri were in that condition in which we would expect to find them when no substance is contained in the uterus.

There was no attempt made at removal of the abnormal abdominal contents through the rectum or vagina, simply because there was no tendency for the *débris* to be ejected by these channels; instead, however, Dr. Playfair preferred to make an opening in the abdominal walls, and to procure extrusion in this manner. With this object in view, a caustic issue was made a little toward the left of the medial line of the abdomen, and inferior to the umbilicus, immediately over one of those projections formed by the fœtal limbs, and where it seemed most likely that the wall of the abdomen would be penetrated, were such an occurrence at all to take place.

It was scarcely anticipated that the patient's strength would carry her through the tedious processes necessary for the extrusion; but yet the procedure was fully justifiable, inasmuch as it was the only one which could give the patient any prospect of escape from the certainty of death by which she was threatened.

This case calls to our mind one which we some time since saw in St. Bartholomew's Hospital, under the care of Dr. Greenhalgh, and which we duly reported at the time that the case was under observation:—The woman had conceived, had advanced in pregnancy, and was one day walking in the street, when she slipped and fell; violent abdominal pain and some constitutional disturbance supervened; her full term came, but, though the time for birth had arrived, no delivery was effected. She went beyond her full time, and it then became apparent that the uterus had been ruptured, that the child had slipped from the womb into the cavity of the abdomen, where it lay, for a time at least, an inoffensive substance, and might remain for a considerable period without creating fatal, or, indeed, any very distressing or even uncomfortable symptoms. After the lapse of some time, an opening was made into the rectum, and fœtal remains—bones, flesh, hair—all in an excellent state of preservation, came away per anum. The case, we believe, ended in the recovery of the patient, and her restoration to perfect health.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

(From the Case-book of MR. MILTON.)

VESICULAR FORM OF ECTHYMA.

This form of ulceration, though painful and obstinate, is not generally described in works on cutaneous diseases. It is not often seen, only three distinct cases having been recorded at this institution during the last sixteen months. Mr. Milton is, however, disposed to think that it might be more frequently observed, though, perhaps, in a less marked form, could we always trace some forms of ecthyma and ulceration of the leg back to their first beginnings; but, as is well known, in the great majority of cases we do not see these patients till ulceration has existed some time. The nature and progress of the disease will perhaps be best understood from a brief narrative of the cases in question:—

E. D., an extremely stout girl, nineteen years of age, applied March 8, 1864, with what she called heat spots on her leg. On examination, three or four small, hard, fiery-red papulæ were seated on the outer side of the lower part of the right leg; one of these was surmounted by an angry-looking vesicle. With the exception of a remarkably dry, cracked state of the skin of the under lip, which was extremely thick, this girl presented every appearance of high health; there were no signs of scabies. She was put upon saline aperients, and a lotion of liquor plumbi and camphor mixture was ordered to be applied to the part. At the next visit it was found that all the other papulæ were dying away, while that on which the vesicle was seated had passed into decided ulceration. She was ordered, for internal use, the acid solution of iron employed at this institution; the sore to be dressed with ung. zinci. Under this she soon recovered.

T. C., a tall, healthy-looking woman, aged thirty, applied with the same complaint. Here, also, there was only one papule on which a vesicle was seated; on the centre of the vesicle was a black dot. The disease had assailed the outer part of the leg just above the ankle. There was no itching, but she had suffered all night from such severe burning and stinging, that she was not only prevented from sleeping, but thoroughly alarmed. She was put upon the same treatment, but the vesicle ulcerated and for some days discharged a quantity of clear serum. It healed without any bad symptoms, but a scar remained.

P. applied Aug. 2, 1864, with this complaint in a much more severe form, nearly the whole of the left leg from the knee to the foot having been attacked at one time or other. Here the complaint was exhibited in every stage; in some places there were merely large papules or tubercles, dark red, very irregularly shaped, some quite an inch and a half long, raised at parts a line or two above the skin. In other places, but very sparingly scattered, were vesicles progressing. Only one vesicle was seen fully formed. Again, in

some of the papules were seated very small but proportionately very deep ulcers, looking quite scooped out, the largest being about the size of half a Spanish nut. Finally, there were some irregular cicatrices. From the ulcers an almost colourless serum was discharged in great abundance, a linen bandage which the patient wore being quite saturated. The chin also was invaded by the disease, but only in the form of papules, of which there were two large ones seated on the under part. The disease had existed several months. The patient had been under medical treatment and had also tried to cure himself, with the usual result. Here, also, no history of scabies could be made out. The patient was at once ordered the acid solution of iron three times a day, and a mild aperient pill two or three times a week; the sore to be dressed with a weak ointment of red nitrate of mercury. At present, the patient is progressing most favourably.

This disease does not correspond with ordinary vesicular or bulbous affections. The irregular thickening and hardening of the base, with its disproportionate size, entirely remove it from that category. The vesicles *never become purulent, nor were any pustules seen.* The vesicles also were not seated on conical elevations, as is the case in ecthyma; nor was the complaint met with in persons of broken-down constitution, or exposed to hardships, want, and inclement weather. There was no history of syphilis—no reason to suspect it—in any of the cases; none of the patients presented any signs of scabies or communicated this disease, though they all slept habitually with other persons; and the treatment adopted was not in any way calculated to cure either of these contagious affections.

PARISIAN MEDICAL NEWS.

HOSPITAL FOR INFANCY.

M. H. ROGER'S CLINICAL WARDS.

Scarlatina.

During the last few months an epidemic, of what M. Roger calls the lesser scarlatina (*scarlatinette*), has been widely prevalent in Paris. The eruption was in general extremely faint, or so very transient, that the nature of the affection often remained undetected. The peculiar poison of scarlet fever was, however, undoubtedly present; and when the patients restored, to all appearance, or, recovering from a seemingly unimportant eruption, were exposed to cold, severe, and sometimes fatal, hematuria or dropsy supervened. In one instance, which it may not be inappropriate to refer to here, terror was the cause which checked the escape of the fever-poison from the skin, and gave rise to anasarca. The patient was a little girl, aged four years, who was supposed to have escaped the contagion of scarlatina, which her sisters had suffered from, and in whom the eruption and sore-throat had been so slight as to escape even the notice of her mother.

Sometimes the eruption presents many of the characters of measles and scarlatina conjoined: such are, for instance, the exanthemata, which have been denominated by various authors *scarlatiniform exanthema, estival roseola, rosalia, rotheln*, and *rash*, and which may or may not coincide with the presence of fever. According to Dr. Almeras, to whom the Profession is indebted for an exhaustive memoir on the subject, it is almost impossible to express, in the incipient stage, a decided opinion as to the true nature of the disease. In the second stage only, the affection assumes the following characters:—Roseate, diffused, dotted eruption; mild angina, unattended with any marked redness; tumefaction of the tonsils, or caseous exudations; the tongue does not present the scarlet colour, nor the strawberry appearance characteristic of genuine scarlatina; the general condition of the patient is usually satisfactory, and the pulse natural. In the third stage desquamation fails, or is confined to furfuraceous exfoliation; the renal secretion is healthy, and no anasarca is observed.

But, as we stated before, although the differences between true and spurious scarlatina are pretty well marked, the points of resemblance are sufficiently numerous to render it difficult during the prevalence of an epidemic to discriminate scarlet fever from the milder exanthema; and the practitioner will act prudently in treating all such cases alike, and in confining within doors, for a fortnight at least, all children who have presented even the faintest appearance of a suspicious eruption. M. Roger further recommends that the patients be isolated from all communication with healthy children, because the risk of scarlatina should never be unnecessarily incurred.

Therefore, in contrast with the well-marked cases of scarlet fever, which from the outset leave no room for any doubt, others not unfrequently occur so faintly characterised as to be easily confounded with eruptions entirely foreign to scarlatina. These spurious forms deserve, notwithstanding their innocuous aspect, very serious attention, because they are not less liable than the others to give rise to one of the most formidable complications of scarlatina, acute desquamative nephritis.

Albuminuria sets in from the fifth to the twelfth day of the eruption; and if the urine is highly albuminous, dropsy follows. According to M. Roger, serous effusions are observed about once in every seven cases, and supervene in the course of the third week of the disease. Experience teaches that exposure to cold is by far the most active cause of scarlatinal anasarca, and that all children affected with scarlet fever should keep their bed a fortnight at least, and be confined to the house for three weeks. After that interval, the development of this complication is improbable. M. Roger is not of opinion that anasarca may supervene at any time during the process of desquamation, and he thinks that in the cases in which dropsy is alleged to have set in at a period more distant from the initial stage of the affection than that mentioned above, it was referable to chronic renal disease, or to acute nephritis unconnected with scarlatina—an occurrence not uncommon in infancy.

The essential point in the matter is, that exposure to cold is the most frequent cause of anasarca, and that every precaution should be taken to guard the patients against such exposure for three weeks, beyond which no further danger need be apprehended.

Vomiting is one of the premonitory symptoms of anasarca; the complication is to feared when, from the tenth to the twentith day of scarlatina, fever and emesis supervene; under these circumstances, forty-eight hours seldom elapse before puffiness of the face makes its appearance. The urine is then scanty, and assumes a smoky colour, which, even without the assistance of the microscope, betrays the presence of blood in the secretion. In fifty per cent. of the cases the affection is confined to anasarca, and in the remainder effusions form in the visceral cavities. If abdominal dropsy alone exists, no very serious apprehensions need be entertained; but the case assumes a more serious aspect if serum accumulates in the pleura, because both sides of the chest are simultaneously affected; and if the pulmonary cellular tissue becomes œdematous, extreme dyspnœa must be the consequence. Œdema of the glottis is sometimes superadded, and has more than once required the performance of tracheotomy. But of all forms of serous effusion, hydrocephalus is by far the most formidable, and may give rise to comatose, paralytic, or convulsive symptoms. M. Roger remarked, that although the occurrence of convulsions must be viewed as an extremely serious complication, a recovery occurs in one-third of the patients.

The only preventive treatment of scarlatinal anasarca consists in guarding against the effects of cold, and in this respect too much caution cannot be displayed. We may therefore repeat with M. Roger, that the child must be kept a fortnight in bed, three weeks in doors, and then be permitted to take open-air exercise in fine weather only This rule admits of no exception.

The curative treatment varies according to the indications in each case. If the skin is hot, the pulse frequent, and the œdematous integument has a roseate hue, venesection is appropriate, more especially if pulmonary œdema be present. The abstraction of blood affords immediate elief, and the lancet is preferable to leeches or cupping,

which may cause erysipelas or an erythematous eruption. Bleeding from the arm is only open to the objection of being difficult of performance, but if practicable it should be resorted to, and four, six, or eight ounces of blood be abstracted. The operation may, if necessary, be repeated.

It is also desirable to promote absorption, by the exhibition of medicines calculated to act on the skin and intestines. Stimulants and diaphoretics are the most useful remedial agents; and M. Roger prefers dry friction to friction with any liquid. Flannel may be used, impregnated with vapours of benzoin, or of juniper berries, or with Fioraventi's balsam. After two or three days a vapour-bath may be prescribed every forty-eight hours, and it is useful to exhibit every day at the same time from half a drachm to one drachm of the liq. ammon. acetatis, in two or three doses, in elder-flower tea.

This is the most appropriate treatment in the acute form. In the chronic variety of the disease, unless any complication requiring blood-letting be present, diuretics, drastics, and reiterated blistering over the chest are the measures most likely to prove serviceable. If the brain is engaged, leeches should be applied to the mastoids, and counter-irritation in the shape of blisters to the nape of the neck or the thighs; hydragogues should be administered, and also from half a drachm to two drachms of nitre in the course of the day. In mild cases, M. Roger prescribes, simultaneously with vapour-baths, nitric acid lemonade, and a mixture containing from eight to fifteen grains of tannin.

Syphilis in Infancy.

M. Roger exhibited in his amphitheatre a number of children affected with syphilis, and a series of coloured plates illustrative of the principal forms of the disease in childhood. The following is a brief abstract of his lectures on this interesting subject:—

The complaint may be hereditary or acquired. In the latter instance the symptoms differ but little from those observed in the adult, except when the taint has been propagated in a peculiar manner—by lactation, for instance, cohabitation, &c.; but the Professor especially dwelt on the pathognomonics of congenital or hereditary syphilis.

The death of the child in utero and abortion are frequent consequences of the transmission of the taint to the fœtus. When three miscarriages occur in succession in the same woman, M. Roger opines that the presence of syphilis should be strongly suspected. The bodies of infants who perish under these circumstances are soft and flabby; the cuticle is detached, exposing the dark hue of the derm; and the viscera also present traces of the infection. M. Depaul has described the fibro-plastic or purulent deposits which occur in the lungs; the lobules are in a state of induration, considered characteristic by M. Alph. Guérin, and the liver presents a flinty colour and a granular aspect to which M. Gubler has called attention.

Supposing, however, that pregnancy has reached its full term, the child may present, in addition to the appearances we have enumerated, and others of a very serious character observable in the thymus and periosteum, an external symptom indicative of syphilis, viz., pemphigus. This is the only secondary eruption which is not ushered in by any premonitory signs, and, although unfrequent, is viewed by M. Roger as pathognomonic. It cannot be mistaken for simple pemphigus, which never breaks out before the sixth, eighth, or even tenth month after birth. The simple form of the disease is moreover discreet, whereas the syphilitic variety is abundant, especially over the palms of the hands and soles of the feet. The contents of the bullæ are serous in the former and puriform in the latter, in which, in addition, the hand assumes a blueish tinge and the complexion a cachectic hue; the bullæ display a tendency to ulceration, and a fatal issue occurs in eleven out of twelve cases doubtless on account of coincident visceral complications. These various circumstances supply a sufficient clue to the diagnosis of syphilitic pemphigus occurring shortly after birth.

When the hereditary taint is not thus immediately revealed by the appearance of pemphigus, no other external manifestations of syphilis occur for a fortnight. Thus, M. Cullerier has only twice in ten years observed symptomatic psoriasis in the first two or three days of extra-uterine life. The presence of the poison in the blood seldom gives rise to papular or pustular manifestations around the anus, in the inguinal region, or to specific coryza before the child is at least a fortnight old. It is doubtless a matter of some import to ascertain the period at which secondaries break out in new-born infants, but it is equally interesting to measure the interval after which they are not likely to recur, in order to be enabled to assert that any syphilitic manifestations which may subsequently be observed are assuredly the result of recent and not of hereditary contamination. Now, statistical returns demonstrate that hereditary syphilis seldom appears after the child has reached the sixth month of his life.

Of 235 instances of hereditary syphilis collected by M. Roger, the symptoms broke out in the course of the first month, and generally in the second fortnight of that month in 112; in 92 cases the secondaries appeared in the second and third months; and in 31 cases only after that date.

M. Ricord, it is true, is of opinion that hereditary syphilis may make its appearance at a much later period, and even when the subject has reached maturity; but although statements made by so eminent an authority are well entitled to confidence, still M. Roger is inclined to think that, in the cases adduced by that learned Professor, there has been some error of diagnosis, and that the contamination must have had a much more recent origin. M. Roger conceives himself, therefore, justified in asserting that if syphilitic manifestations are observed for the first time in a child of eight months, and *à fortiori* of one or two years of age, they must not be referred to a congenital, but to an accidentally acquired taint.

We may infer from these remarks that a child may be born with the poison in his system, and yet present for a fortnight the outward appearance of perfect health. Others, on the contrary, have a distressing aged aspect, and, having already reached the latest stage of secondary disease, are, indeed, at death's door. In most instances they are extremely feeble, and are sometime covered with pemphigus. When the affection sets in at the usual period, the integument assumes a characteristic dark brown hue, and at the same time various eruptions appear together with the special coryza.

This chronic irritation of the Schneiderian membrane is essentially different from that which is consequent on exposure to cold. The latter usually supervenes two or three days after the infant's birth, and coincides with epiphora and bronchitis. Syphilitic coryza at first occasions dryness of the mucous membrane and impedes the breathing; a sero-purulent secretion soon follows, sometimes tinged with blood, and containing squamæ, which indicate superficial ulceration; hence the manifestation of coryza in a new-born child requires a considerable degree of attention.

The concomitant eruptions generally consist in roseola, psoriasis of the palm of the hand and sole of the foot, and often specific onyxis. M. Roger also pointed out the frequency of mucous tubercles of the mouth and of the anal regions.

Tertiaries are seldom the result of hereditary syphilis. When appropriate measures of treatment have been resorted to in time, the symptoms which bear a resemblance to tertiary manifestations should, in general, be referred to scrofula or rachitis.

After thus briefly describing the symptoms, amongst which should be noticed frequent diarrhœa, and an unfavourable condition of the entire system, M. Roger inquired into the origin of congenital syphilis, and dwelt on the separate influence of each of the parents, and upon the joint influence of both on the disease transmitted to their offspring.

The influence of the mother in producing infantile syphilis is obvious. A woman labouring under the disease at the period of conception must infallibly communicate the taint to her child. She may not, however, be alone in fault, and the father may, doubtless, be fairly assumed to have had some share in conveying the infection to the infant. Cases are, nevertheless, on record in which the male parent

had most distinctly no part whatever in the transmission, and in which the exclusive influence of the mother was plainly manifest. The same remarks apply to cases in which the disease has been contracted during pregnancy. The free interchange of the elements of the blood between the fœtus and the mother justifies the belief that the child can scarcely escape contamination. As to the latest period of pregnancy at which a woman thus infected can transmit the disease to her infant, numerous facts have demonstrated that when the taint has been communicated to the mother after the conclusion of the seventh month, it is not, in any case, transmitted to the child.

We may now inquire what is likely to be the result when the father alone is affected with syphilis, the mother remaining free from disease? The question has given rise to much controversy, and specialists are not yet agreed as to the solution. MM. Vassal and Cullerier utterly deny that any poisonous influence is exercised under the circumstances by the father, whereas M. Trousseau throws, in most cases, the blame on the male parent; and M. Emile Vidal (Competition for the Fellowship, 1860) relates three cases in which the *exclusive* influence of the father is unquestionably demonstrated.

Facts of this description cannot, moreover, occasion much surprise, when we reflect on the resemblance of children to their father in feature, and also in morbid aptitudes, constitution, and even idiosyncrasy.

Several interesting questions arise as to the period of syphilis at which a father is likely to procreate a diseased child, also as to the possibility of transmission when, at the date of conception, the male parent is not labouring under discernible symptoms; and if mercurial treatment exhibited at this date has any, and what, influence on the embryo, and subsequently on the health of the infant? M. Ricord is of opinion that syphilis is transmissible to the embryo during the secondary stage only, a father affected with tertiary disease communicating nought to his offspring but a marked scrofulous tendency.

It is further generally conceded that paternal syphilis may be handed down to the child before any symptom has appeared on the person of the father or in the interval between two eruptions, as readily as when his body is covered with characteristic stains or pustules. Careful observation has also undeniably established the fact that a man who has apparently been perfectly cured may still, after a long interval, transmit the taint to his child. Finally, several cases on record justify the assumption that the medicines administered to the father at the period of conception are not without their influence on the health of the fœtus.

When both father and mother are contaminated, but slender hope can be entertained that their union will result in a healthy child. Its only chance of escape is that the diathesis of the parents may be of long standing, and weakened by time or by more or less protracted treatment.

Finally, when both parents are diseased, and have undergone no treatment whatever, it does not necessarily follow that all the children born of such a marriage must also inherit the taint. The first two or three infants generally perish in utero; the next child usually presents unmistakable symptoms of syphilis either at the time of its birth or soon after; but all those born afterwards are habitually healthy and uncontaminated by the morbid poison. It may also happen that a sound child is born between two which are infected, the fact being referable to what Melchior Robert terms an *armistice*, or a temporary suspension of the diathesis, or to the accidental predominance of the influence of one of the parents who happens at the time to be cured. This is not a mere supposition, and in his valuable treatise on *Infantile Syphilis* M. Diday adduces a conclusive case of the kind. A woman had been intimate with a man affected with the disease, and subsequently presented characteristic symptoms. She married another individual, and gave birth to several healthy children; but her intercourse with the former lover having been renewed, she became gravid, and bore a child who died of the consequences of a syphilitic eruption.

We shall take an early opportunity of adverting to the pathology of accidental contamination in children, and we shall conclude with M. Roger's remarks on the treatment of both the congenital and acquired forms of the disease.—'Journal of Practical Medicine and Surgery.'

THE HOSPITAL CONVENTION.

The International Congress, which has been sitting at Geneva with a view to regulate the position of hospitals and wounded in time of war, has terminated its labours.

Ten resolutions have been adopted and signed, under reserve of ratification, by the representatives of Belgium, Baden, Denmark, Spain, France, Hesse, Italy, the Netherlands, Portugal, Prussia, Switzerland, and Wurtemburg. The resolutions differ considerably from the programme first issued. They are as follows:—

"Art. 1. Ambulances and military hospitals are regarded as neutral, and, as such, protected and respected by the belligerents (as long as they contain sick or wounded). The neutrality would cease should such hospitals have a military guard.

"Art. 2. All *employés* of the hospital, including the almoners, carriers of the wounded, &c., will enjoy the benefits of this neutrality as long as there are wounded to be attended to.

"Art. 3. The persons designated in the above article may, even after occupation by the enemy, continue to perform their duties in the hospital or ambulance to which they may be attached, or withdraw to join the division to which they may belong.

"Under these circumstances, when their functions shall have ceased they will be escorted to the enemy's outposts by the army in occupation.

"Art. 4. As the *matériel* of military hospitals comes under martial law, the persons attached to those hospitals may not, on leaving, take away with them anything except what is their own personal property.

"Under the same circumstances, however, an ambulance preserves its *matériel*.

"Art. 5. Inhabitants of the country who give help to the wounded are respected and remain free. The generals of the belligerent Powers are called upon to forewarn the inhabitants of the call made upon their humanity, and of the neutrality consequent thereupon.

"Any wounded man taken into a house will be its safeguard. Any inhabitant who has taken in the wounded will not be billeted upon or submitted to war contributions.

"Art. 6. The wounded or sick are taken care of, no matter to what nation they belong.

"Those will be sent back to their homes who, after being cured, are deemed incapable of further service.

"The others may also be sent home, but on the conditions of not resuming arms during the war.

"The escorts on this service are to be respected as neutrals.

"The Commanders-in-Chief have the power to hand over to the enemy's outposts the wounded during the combat when circumstances permit it, and with the consent of both parties.

"Art. 7. A distinct flag and uniform is adopted for the hospitals, ambulances, and escorts. On all occasions the national flag must accompany it.

"A badge may also be allowed to denote a neutral, to be granted only by the military authorities.

"The flag and badge will bear a red cross on a white ground.

"Art. 8. The general details of these regulations will be settled by the commanding officers of the belligerent Powers, according to the instructions from their Governments."

Article 9 calls the attention of other Governments to this Convention, inviting them to join it. Article 10 states that the ratification of the Convention is to take place at Berne within four months, and earlier if possible.

THE MEDICAL CIRCULAR.

WEDNESDAY, SEPTEMBER 7, 1864.

MEDICINE IN ITS RELATIONS TO THE STATE.

It is not at all easy to understand why the Profession of Medicine should be held by our Legislators as inferior to that of the Church or the Law; for however incumbent it may be on a Government to watch over the spiritual welfare of a people, or to protect them in the possession of their property and their civil rights, it is surely also of importance to watch over the maintenance of their health by guarding them against the deleterious influences which surround them, and by teaching them the laws by which the human frame is related to the outer material world. It is useless to argue that mankind are able to take care of themselves in this respect, for experience, no less than common observation, proves that they are not; inasmuch as the elements of disease often lie lurking in the air or the water, or in the food of man, and the detection of these poisons requires the utmost refinement of analytical knowledge, such as the common people cannot be expected to possess. The danger, which is unseen, is too often, and, indeed, most generally, despised—*causa latet, vis est notissima*—and the outbreaks of disease or the inroads of death are the only popular indications of injurious influences which the eye of Science might have penetrated, and from which the finger of experience might have warned the unwary.

It is, therefore, gratifying to find that the general newspapers are beginning to insist upon the application of sanitary laws to the well-being of the community; and although their articles on the subject are now being published, perhaps *faute de mieux*, because the writers have no more exciting topic to engage their pens, yet it is better they should appear now than not at all: and even though they may fail to produce such immediate results as they might do if Parliament were sitting and the metropolis full of residents and visitors, yet the truths and, we may add, the exaggerations which they contain may produce a beneficial effect.

Without arrogating too much for the Medical Profession, we may assert that it has always been foremost, not only in combating disease when it is actually present, but also in endeavouring to avert its attacks; and its influence in the latter respect is peculiarly owing to the nature of the studies in which the practitioner of Medicine is necessarily engaged. The detection of noxious ingredients in air, water, and food is not in the province of the theologian, the lawyer, the statesman, or the architect, but in that of the physician, who, although as yet unable to apply the strict principles of analytical chemistry to the subtle miasmata which lurk in the circumjacent elements, can still apply to these mysterious agencies the same processes of reasoning which belong to the material particles with which science has made him familiar.

The revelations of mismanagement in our Indian possessions, made in a Report published more than a year ago, are only now, perhaps, known to the general public, in consequence of their appearance last week in the columns of the 'Times'; and the same Journal is also giving the benefit of its circulation to the ventilation of sanitary questions more nearly affecting the population of our own islands, and discussed in the volume lately issued by the Medical Department of the Privy Council. In the former record, the scene of which is laid in a country vast in extent, and abounding in animal and vegetable life, the ravages of preventible disease may be studied on a comprehensive scale, and the consequences of sanitary neglect may be conspicuously traced; while in the latter the subjects of discussion lie within a more narrow compass, but are no less interesting to the sanitarian, the philanthropist, and the legislator.

The causes of disease and death in our Indian army, and the means to be adopted for their removal, were fully explained by us at the time of the publication of the Report of the Commissioners; and it is to be hoped that the remarks made by ourselves and others at that period have already led to the adoption of such measures as may tend to reduce the frightful mortality which has hitherto decimated our troops, and has rendered Indian service synonymous with a life of peril and a temptation of fate. It was proved by the most conclusive evidence that, although the climate of India was, in some measure, indubitably inimical to the European constitution, yet the majority of those who suffered or sunk under disease had succumbed from the consequences of their own imprudence, or from the neglect of those sanitary laws which, whether in Europe or in Asia, it is impossible to ignore with impunity. Many as are the casualties to which the soldier is exposed in the active duties of his calling, the deaths from wounds and accidents in battle are almost insignificant in proportion to those which are due to individual excesses, or to the absence of cleanliness and of ventilation, and of other obvious precautions against the inroads of endemic or epidemic disease.

The Annual Report of Mr. Simon, the Medical Officer of the Privy Council, treats of a number of questions, many of which have been discussed in our columns, and all of which require to be impressed upon the minds of the general public, with a view to improvement in many matters of great importance in a sanitary point of view. In the first place, Mr. Simon draws attention, as he has done on many previous occasions, to the shamefully inefficient manner in which vaccination is conducted in this country, and he gives the details of an inspection of 1,143 vaccination districts in proof of the statements and arguments which he advances. Hitherto, as is too well known, his warnings, and those of the Medical Press, have been unheeded, and a preventible scourge to the community has been allowed to continue its ravages, instead of being extirpated, as it might have been, under a vigorous and effective system of sanitary legislation. The very absurd argument, that a compulsory system of vaccination would

interfere with the liberty of the subject, has been abandoned in the case of another disease which is, and always has been, under individual control; and as the Legislature, in its wisdom, has seen fit to throw the shield of its protection over our soldiers and sailors, by obviating the chances of one kind of contagion, it is only fair to hope and expect that the same protection will be afforded to our helpless infants, in guarding them against the ravages of small-pox, with its attendant perils to life, and its baneful consequences even to those who survive its attack.

The relative amount of food consumed by the poorer classes of the population, whether we include those engaged in in-door employment or in agricultural labour, and the connexion of this food-supply with the prevalence of disease, is another important topic of investigation in Mr. Simon's Report. Dr. Edward Smith, who has specially inquired into this subject, furnishes much valuable information; and founding his conclusions upon chemical and physiological bases, affords to the general public some useful hints of which they are very much in need. The ignorance of the fundamental principles of chemistry among those who regulate the diet of the poor is lamentable indeed, and involves an enormous waste of money, besides entailing an immense amount of suffering and disease. Not that we accept, *au pied de la lettre*, every chemical statement we receive, or that we believe that the human stomach and the human absorbents are nothing more or less than chemical retorts and analysing tubes; for it is an undoubted truth that the same amount of food which would be too much for the agricultural labourer may be too little for the pallid artisan working in a close and crowded manufactory. Still, *cæteris paribus*, there are certain chemical laws which cannot be ignored; and it is as hopeless an attempt, for instance, to nourish the human body with carbonaceous food, however varied, as it would be to extract sunbeams from cucumbers, as was proposed by the philosophers of Laputa. It is also very important to communicate such information as that furnished by Dr. Smith, to the effect that buttermilk contains more nutritious material than tea; but, unfortunately, Dr. Smith's practical deduction from this principle, that three-pennyworth of buttermilk amounts to twelve pints (at least in Devonshire), and that three-pennyworth of tea amounts only to a few drachms, is untrue, as far as the buttermilk is concerned. Buttermilk is by no means so cheap, even in Devonshire, as Dr. Smith asserts; and, indeed, the peasantry, in many rural districts, cannot procure buttermilk at all.

There are many other topics of great interest discussed in Mr. Simon's Report, to the consideration of which we shall revert on some future occasion.

MEETING OF THE GERMAN PHYSICIANS AND NATURALISTS.—It has been determined to hold the next meeting at Giessen, from the 17th to 23rd September. The managers, Professors Wernher, Leuckart, and Vogt, of the Giessen University, assure the expected guests of the warmest reception on the part of this celebrated city.

SUMMARY OF THE WEEK.

SEWAGE AT THE SEA-SIDE.
